Certbot is part of EFF’s effort to encrypt the entire Internet. Secure communication over the Web relies on HTTPS, which requires the use of a digital certificate that lets browsers verify the identity of web servers (e.g., is that really google.com?). Web servers obtain their certificates from trusted third parties called certificate authorities (CAs). Certbot is an easy-to-use client that fetches a certificate from Let’s Encrypt—an open certificate authority launched by the EFF, Mozilla, and others—and deploys it to a web server.

Anyone who has gone through the trouble of setting up a secure website knows what a hassle getting and maintaining a certificate is. Certbot and Let’s Encrypt can automate away the pain and let you turn on and manage HTTPS with simple commands. Using Certbot and Let’s Encrypt is free, so there’s no need to arrange payment.

How you use Certbot depends on the configuration of your web server. The best way to get started is to use our interactive guide. It generates instructions based on your configuration settings. In most cases, you’ll need root or administrator access to your web server to run Certbot.

Certbot is meant to be run directly on your web server, not on your personal computer. If you’re using a hosted service and don’t have direct access to your web server, you might not be able to use Certbot. Check with your hosting provider for documentation about uploading certificates or using certificates issued by Let’s Encrypt.

Certbot is a fully-featured, extensible client for the Let’s Encrypt CA (or any other CA that speaks the ACME protocol) that can automate the tasks of obtaining certificates and configuring webservers to use them. This client runs on Unix-based operating systems.

To see the changes made to Certbot between versions please refer to our changelog.

1.1 Contributing

If you’d like to contribute to this project please read Developer Guide.

This project is governed by EFF’s Public Projects Code of Conduct.
1.2 How to run the client

The easiest way to install and run Certbot is by visiting certbot.eff.org, where you can find the correct instructions for many web server and OS combinations. For more information, see Get Certbot.

1.3 Understanding the client in more depth

To understand what the client is doing in detail, it’s important to understand the way it uses plugins. Please see the explanation of plugins in the User Guide.

1.3.2 System Requirements

See https://certbot.eff.org/docs/install.html#system-requirements.
WHAT IS A CERTIFICATE?

A public key or digital certificate (formerly called an SSL certificate) uses a public key and a private key to enable secure communication between a client program (web browser, email client, etc.) and a server over an encrypted SSL (secure socket layer) or TLS (transport layer security) connection. The certificate is used both to encrypt the initial stage of communication (secure key exchange) and to identify the server. The certificate includes information about the key, information about the server identity, and the digital signature of the certificate issuer. If the issuer is trusted by the software that initiates the communication, and the signature is valid, then the key can be used to communicate securely with the server identified by the certificate. Using a certificate is a good way to prevent “man-in-the-middle” attacks, in which someone in between you and the server you think you are talking to is able to insert their own (harmful) content.

You can use Certbot to easily obtain and configure a free certificate from Let’s Encrypt, a joint project of EFF, Mozilla, and many other sponsors.

2.1 Certificates and Lineages

Certbot introduces the concept of a lineage, which is a collection of all the versions of a certificate plus Certbot configuration information maintained for that certificate from renewal to renewal. Whenever you renew a certificate, Certbot keeps the same configuration unless you explicitly change it, for example by adding or removing domains. If you add domains, you can either add them to an existing lineage or create a new one.

3.1 About Certbot

Certbot is meant to be run directly on a web server, normally by a system administrator. In most cases, running Certbot on your personal computer is not a useful option. The instructions below relate to installing and running Certbot on a server.

System administrators can use Certbot directly to request certificates; they should not allow unprivileged users to run arbitrary Certbot commands as root, because Certbot allows its user to specify arbitrary file locations and run arbitrary scripts.

Certbot is packaged for many common operating systems and web servers. Check whether certbot (or letsencrypt) is packaged for your web server’s OS by visiting certbot.eff.org, where you will also find the correct installation instructions for your system.

Note: Unless you have very specific requirements, we kindly suggest that you use the installation instructions for your system found at certbot.eff.org.
3.2 System Requirements

Certbot currently requires Python 3.6+ running on a UNIX-like operating system. By default, it requires root access in order to write to /etc/letsencrypt, /var/log/letsencrypt, /var/lib/letsencrypt; to bind to port 80 (if you use the standalone plugin) and to read and modify webserver configurations (if you use the apache or nginx plugins). If none of these apply to you, it is theoretically possible to run without root privileges, but for most users who want to avoid running an ACME client as root, either letsencrypt-nosudo or simp_le are more appropriate choices.

The Apache plugin currently requires an OS with augeas version 1.0; currently it supports modern OSes based on Debian, Ubuntu, Fedora, SUSE, Gentoo and Darwin.

3.3 Alternate installation methods

If you are offline or your operating system doesn’t provide a package, you can use an alternate method for installing certbot.

3.3.1 Snap

Most modern Linux distributions (basically any that use systemd) can install Certbot packaged as a snap. Snaps are available for x86_64, ARMv7 and ARMv8 architectures. The Certbot snap provides an easy way to ensure you have the latest version of Certbot with features like automated certificate renewal preconfigured.

You can find instructions for installing the Certbot snap at https://certbot.eff.org/instructions by selecting your server software and then choosing “snapd” in the “System” dropdown menu. (You should select “snapd” regardless of your operating system, as our instructions are the same across all systems.)

3.3.2 Running with Docker

Docker is an amazingly simple and quick way to obtain a certificate. However, this mode of operation is unable to install certificates or configure your webserver, because our installer plugins cannot reach your webserver from inside the Docker container.

Most users should use the instructions at certbot.eff.org. You should only use Docker if you are sure you know what you are doing and have a good reason to do so.

You should definitely read the Where are my certificates? section, in order to know how to manage the certificates manually. Our ciphersuites page provides some information about recommended ciphersuites. If none of these make much sense to you, you should definitely use the installation method recommended for your system at certbot.eff.org, which enables you to use installer plugins that cover both of those hard topics.

If you’re still not convinced and have decided to use this method, from the server that the domain you’re requesting a certificate for resolves to, install Docker, then issue a command like the one found below. If you are using Certbot with the Standalone plugin, you will need to make the port it uses accessible from outside of the container by including something like -p 80:80 or -p 443:443 on the command line before certbot/certbot.

```bash
sudo docker run -it --rm --name certbot \
-v "/etc/letsencrypt:/etc/letsencrypt" \
-v "/var/lib/letsencrypt:/var/lib/letsencrypt" \
certbot/certbot certonly
```
Running Certbot with the `certonly` command will obtain a certificate and place it in the directory `/etc/letsencrypt/live` on your system. Because Certonly cannot install the certificate from within Docker, you must install the certificate manually according to the procedure recommended by the provider of your webserver.

There are also Docker images for each of Certbot’s DNS plugins available at https://hub.docker.com/u/certbot which automate doing domain validation over DNS for popular providers. To use one, just replace `certbot/certbot` in the command above with the name of the image you want to use. For example, to use Certbot’s plugin for Amazon Route 53, you’d use `certbot/dns-route53`. You may also need to add flags to Certbot and/or mount additional directories to provide access to your DNS API credentials as specified in the DNS plugin documentation.

For more information about the layout of the `/etc/letsencrypt` directory, see Where are my certificates?.

### 3.3.3 Operating System Packages

**Warning:** While the Certbot team tries to keep the Certbot packages offered by various operating systems working in the most basic sense, due to distribution policies and/or the limited resources of distribution maintainers, Certbot OS packages often have problems that other distribution mechanisms do not. The packages are often old resulting in a lack of bug fixes and features and a worse TLS configuration than is generated by newer versions of Certbot. They also may not configure certificate renewal for you or have all of Certbot’s plugins available. For reasons like these, we recommend most users follow the instructions at https://certbot.eff.org/instructions and OS packages are only documented here as an alternative.

**Arch Linux**

```
sudo pacman -S certbot
```

**Debian**

If you run Debian Buster or Debian testing/Sid, you can easily install certbot packages through commands like:

```
sudo apt-get update
sudo apt-get install certbot
```

If you run Debian Stretch, we recommend you use the packages in Debian backports repository. First you’ll have to follow the instructions at https://backports.debian.org/Instructions/ to enable the Stretch backports repo, if you have not already done so. Then run:

```
sudo apt-get install certbot -t stretch-backports
```

In all of these cases, there also packages available to help Certbot integrate with Apache, nginx, or various DNS services. If you are using Apache or nginx, we strongly recommend that you install the `python-certbot-apache` or `python-certbot-nginx` package so that Certbot can fully automate HTTPS configuration for your server. A full list of these packages can be found through a command like:

```
apt search 'python-certbot*'
```

They can be installed by running the same installation command above but replacing `certbot` with the name of the desired package.

**Ubuntu**

If you run Ubuntu, certbot can be installed using:

```
sudo apt-get install certbot
```

3.3. Alternate installation methods
Optionally to install the Certbot Apache plugin, you can use:

```
sudo apt-get install python3-certbot-apache
```

**Fedora**

```
sudo dnf install certbot python3-certbot-apache
```

**FreeBSD**

- **Port:** cd /usr/ports/security/py-certbot && make install clean
- **Package:** pkg install py37-certbot

**Gentoo**

The official Certbot client is available in Gentoo Portage. From the official Certbot plugins, three of them are also available in Portage. They need to be installed separately if you require their functionality.

```
emerge -av app-crypt/certbot
emerge -av app-crypt/certbot-apache
emerge -av app-crypt/certbot-nginx
emerge -av app-crypt/certbot-dns-nsone
```

**Note:** The app-crypt/certbot-dns-nsone package has a different maintainer than the other packages and can lag behind in version.

**NetBSD**

- **Build from source:** cd /usr/pkgsrc/security/py-certbot && make install clean
- **Install pre-compiled package:** pkg_add py37-certbot

**OpenBSD**

- **Port:** cd /usr/ports/security/letsencrypt/client && make install clean
- **Package:** pkg_add letsencrypt

**Other Operating Systems**

OS packaging is an ongoing effort. If you’d like to package Certbot for your distribution of choice please have a look at the [Packaging Guide](#).

### 3.3.4 Certbot-Auto

**Uninstalling certbot-auto**

To uninstall `certbot-auto`, you need to do three things:

1. If you added a cron job or systemd timer to automatically run `certbot-auto` to renew your certificates, you should delete it. If you did this by following our instructions, you can delete the entry added to `/etc/crontab` by running a command like sudo sed -i '/certbot-auto/d' /etc/crontab.

2. Delete the `certbot-auto` script. If you placed it in `/usr/local/bin` like we recommended, you can delete it by running `sudo rm /usr/local/bin/certbot-auto`.

3. Delete the Certbot installation created by `certbot-auto` by running `sudo rm -rf /opt/eff.org`. 
We used to have a shell script named `certbot-auto` to help people install Certbot on UNIX operating systems, however, this script is no longer supported. If you want to uninstall `certbot-auto`, you can follow our instructions [here](#).

### 3.3.5 Pip

Installing Certbot through pip is only supported on a best effort basis and when using a virtual environment. Instructions for installing Certbot through pip can be found at [https://certbot.eff.org/instructions](https://certbot.eff.org/instructions) by selecting your server software and then choosing “pip” in the “System” dropdown menu.

4.1 Certbot Commands

Certbot uses a number of different commands (also referred to as “subcommands”) to request specific actions such as obtaining, renewing, or revoking certificates. The most important and commonly-used commands will be discussed throughout this document; an exhaustive list also appears near the end of the document.

The certbot script on your web server might be named letsencrypt if your system uses an older package, or certbot-auto if you used a now-deprecated installation method. Throughout the docs, whenever you see certbot, swap in the correct name as needed.

4.2 Getting certificates (and choosing plugins)

The Certbot client supports two types of plugins for obtaining and installing certificates: authenticators and installers. Authenticators are plugins used with the certonly command to obtain a certificate. The authenticator validates that you control the domain(s) you are requesting a certificate for, obtains a certificate for the specified domain(s), and places the certificate in the /etc/letsencrypt directory on your machine. The authenticator does not install the certificate (it does not edit any of your server’s configuration files to serve the obtained certificate). If you specify multiple domains to authenticate, they will all be listed in a single certificate. To obtain multiple separate certificates you will need to run Certbot multiple times.

Installers are Plugins used with the install command to install a certificate. These plugins can modify your web-server’s configuration to serve your website over HTTPS using certificates obtained by certbot.

Plugins that do both can be used with the certbot run command, which is the default when no command is specified. The run subcommand can also be used to specify a combination of distinct authenticator and installer plugins.

</tr>
</tbody>
</table>

4.2. Getting certificates (and choosing plugins)
Under the hood, plugins use one of several ACME protocol challenges to prove you control a domain. The options are http-01 (which uses port 80) and dns-01 (requiring configuration of a DNS server on port 53, though that’s often not the same machine as your webserver). A few plugins support more than one challenge type, in which case you can choose one with --preferred-challenges.

There are also many third-party-plugins available. Below we describe in more detail the circumstances in which each plugin can be used, and how to use it.

4.2.1 Apache

The Apache plugin currently supports modern OSes based on Debian, Fedora, SUSE, Gentoo and Darwin. This automates both obtaining and installing certificates on an Apache webserver. To specify this plugin on the command line, simply include --apache.

4.2.2 Webroot

If you’re running a local webserver for which you have the ability to modify the content being served, and you’d prefer not to stop the webserver during the certificate issuance process, you can use the webroot plugin to obtain a certificate by including certonly and --webroot on the command line. In addition, you’ll need to specify --webroot-path or -w with the top-level directory (“web root”) containing the files served by your webserver. For example, --webroot-path /var/www/html or --webroot-path /usr/share/nginx/html are two common webroot paths.

If you’re getting a certificate for many domains at once, the plugin needs to know where each domain’s files are served from, which could potentially be a separate directory for each domain. When requesting a certificate for multiple domains, each domain will use the most recently specified --webroot-path. So, for instance,

```
certbot certonly --webroot -w /var/www/example -d www.example.com -d example.com -w /var/www/other -d other.example.net
```

would obtain a single certificate for all of those names, using the /var/www/example webroot directory for the first two, and /var/www/other for the second two.

The webroot plugin works by creating a temporary file for each of your requested domains in ${webroot-path}/.well-known/acme-challenge. Then the Let’s Encrypt validation server makes HTTP requests to validate that the DNS for each requested domain resolves to the server running certbot. An example request made to your web server would look like:

```
66.133.109.36 - - [05/Jan/2016:20:11:24 -0500] "GET /.well-known/acme-challenge/HGr8UlIeTW4kY_26U1yaakz0kyQgPr_7ArlLgt2E8SX HTTP/1.1" 200 87 "-" "Mozilla/5.0 (compatible; Let's Encrypt validation server; +https://www.letsencrypt.org)"
```

Note that to use the webroot plugin, your server must be configured to serve files from hidden directories. If /.well-known is treated specially by your webserver configuration, you might need to modify the configuration to ensure that files inside /.well-known/acme-challenge are served by the webserver.
4.2.3 Nginx

The Nginx plugin should work for most configurations. We recommend backing up Nginx configurations before using it (though you can also revert changes to configurations with `certbot --nginx rollback`). You can use it by providing the `--nginx` flag on the commandline.

```bash
certbot --nginx
```

4.2.4 Standalone

Use standalone mode to obtain a certificate if you don’t want to use (or don’t currently have) existing server software. The standalone plugin does not rely on any other server software running on the machine where you obtain the certificate.

To obtain a certificate using a “standalone” webserver, you can use the standalone plugin by including `certonly` and `--standalone` on the command line. This plugin needs to bind to port 80 in order to perform domain validation, so you may need to stop your existing webserver.

It must still be possible for your machine to accept inbound connections from the Internet on the specified port using each requested domain name.

By default, Certbot first attempts to bind to the port for all interfaces using IPv6 and then bind to that port using IPv4; Certbot continues so long as at least one bind succeeds. On most Linux systems, IPv4 traffic will be routed to the bound IPv6 port and the failure during the second bind is expected.

Use `--<challenge-type>-address` to explicitly tell Certbot which interface (and protocol) to bind.

4.2.5 DNS Plugins

If you’d like to obtain a wildcard certificate from Let’s Encrypt or run `certbot` on a machine other than your target webserver, you can use one of Certbot’s DNS plugins.

These plugins are not included in a default Certbot installation and must be installed separately. They are available in many OS package managers, as Docker images, and as snaps. Visit [https://certbot.eff.org](https://certbot.eff.org) to learn the best way to use the DNS plugins on your system.

Once installed, you can find documentation on how to use each plugin at:

- `certbot-dns-cloudflare`
- `certbot-dns-cloudxns`
- `certbot-dns-digitalocean`
- `certbot-dns-dnssimple`
- `certbot-dns-dnsmadeeasy`
- `certbot-dns-gehirn`
- `certbot-dns-google`
- `certbot-dns-linode`
- `certbot-dns-1uatdns`
- `certbot-dns-nsone`
- `certbot-dns-ovh`
- `certbot-dns-rfc2136`
4.2.6 Manual

If you’d like to obtain a certificate running certbot on a machine other than your target webserver or perform the steps for domain validation yourself, you can use the manual plugin. While hidden from the UI, you can use the plugin to obtain a certificate by specifying certonly and --manual on the command line. This requires you to copy and paste commands into another terminal session, which may be on a different computer.

The manual plugin can use either the http or the dns challenge. You can use the --preferred-challenges option to choose the challenge of your preference.

The http challenge will ask you to place a file with a specific name and specific content in the /.well-known/acme-challenge/ directory directly in the top-level directory (“web root”) containing the files served by your webserver. In essence it’s the same as the webroot plugin, but not automated.

When using the dns challenge, certbot will ask you to place a TXT DNS record with specific contents under the domain name consisting of the hostname for which you want a certificate issued, prepended by _acme-challenge.

For example, for the domain example.com, a zone file entry would look like:

```plaintext
_acme-challenge.example.com. 300 IN TXT "gfj9Xq...Rg85nM"
```

Additionally you can specify scripts to prepare for validation and perform the authentication procedure and/or clean up after it by using the --manual-auth-hook and --manual-cleanup-hook flags. This is described in more depth in the hooks section.

4.2.7 Combining plugins

Sometimes you may want to specify a combination of distinct authenticator and installer plugins. To do so, specify the authenticator plugin with --authenticator or -a and the installer plugin with --installer or -i.

For instance, you could create a certificate using the webroot plugin for authentication and the apache plugin for installation.

```plaintext
certbot run -a webroot -i apache -w /var/www/html -d example.com
```

Or you could create a certificate using the manual plugin for authentication and the nginx plugin for installation. (Note that this certificate cannot be renewed automatically.)

```plaintext
certbot run -a manual -i nginx -d example.com
```

4.2.8 Third-party plugins

There are also a number of third-party plugins for the client, provided by other developers. Many are beta/experimental, but some are already in widespread use:
If you’re interested, you can also write your own plugin.

### 4.3 Managing certificates

To view a list of the certificates Certbot knows about, run the `certificates` subcommand:

```
certbot certificates
```

This returns information in the following format:

```
Found the following certificates:
Certificate Name: example.com
  Domains: example.com, www.example.com
  Expiry Date: 2017-02-19 19:53:00+00:00 (VALID: 30 days)
  Certificate Path: /etc/letsencrypt/live/example.com/fullchain.pem
  Key Type: RSA
  Private Key Path: /etc/letsencrypt/live/example.com/privkey.pem
```

Certificate Name shows the name of the certificate. Pass this name using the `--cert-name` flag to specify a particular certificate for the `run`, `certonly`, `certificates`, `renew`, and `delete` commands. Example:

```
certbot certonly --cert-name example.com
```

#### 4.3.1 Re-creating and Updating Existing Certificates

You can use `certonly` or `run` subcommands to request the creation of a single new certificate even if you already have an existing certificate with some of the same domain names.

If a certificate is requested with `run` or `certonly` specifying a certificate name that already exists, Certbot updates the existing certificate. Otherwise a new certificate is created and assigned the specified name.

The `--force-renewal`, `--duplicate`, and `--expand` options control Certbot’s behavior when re-creating a certificate with the same name as an existing certificate. If you don’t specify a requested behavior, Certbot may ask you what you intended.

`--force-renewal` tells Certbot to request a new certificate with the same domains as an existing certificate. Each domain must be explicitly specified via `--d`. If successful, this certificate is saved alongside the earlier one and symbolic links (the “live” reference) will be updated to point to the new certificate. This is a valid method of renewing a specific individual certificate.
--duplicate tells Certbot to create a separate, unrelated certificate with the same domains as an existing certificate. This certificate is saved completely separately from the prior one. Most users will not need to issue this command in normal circumstances.

--expand tells Certbot to update an existing certificate with a new certificate that contains all of the old domains and one or more additional new domains. With the --expand option, use the -d option to specify all existing domains and one or more new domains.

Example:

```
certbot --expand -d existing.com,example.com,newdomain.com
```

If you prefer, you can specify the domains individually like this:

```
certbot --expand -d existing.com -d example.com -d newdomain.com
```

Consider using --cert-name instead of --expand, as it gives more control over which certificate is modified and it lets you remove domains as well as adding them.

--allow-subset-of-names tells Certbot to continue with certificate generation if only some of the specified domain authorizations can be obtained. This may be useful if some domains specified in a certificate no longer point at this system.

Whenever you obtain a new certificate in any of these ways, the new certificate exists alongside any previously obtained certificates, whether or not the previous certificates have expired. The generation of a new certificate counts against several rate limits that are intended to prevent abuse of the ACME protocol, as described here.

### 4.3.2 Changing a Certificate’s Domains

The --cert-name flag can also be used to modify the domains a certificate contains, by specifying new domains using the -d or --domains flag. If certificate example.com previously contained example.com and www.example.com, it can be modified to only contain example.com by specifying only example.com with the -d or --domains flag. Example:

```
certbot certonly --cert-name example.com -d example.com
```

The same format can be used to expand the set of domains a certificate contains, or to replace that set entirely:

```
certbot certonly --cert-name example.com -d example.org,www.example.org
```

### 4.3.3 Using ECDSA keys

As of version 1.10, Certbot supports two types of private key algorithms: rsa and ecdsa. The type of key used by Certbot can be controlled through the --key-type option. You can also use the --elliptic-curve option to control the curve used in ECDSA certificates.

**Warning:** If you obtain certificates using ECDSA keys, you should be careful not to downgrade your Certbot installation since ECDSA keys are not supported by older versions of Certbot. Downgrades like this are possible if you switch from something like the snaps or pip to packages provided by your operating system which often lag behind.
Changing existing certificates from RSA to ECDSA

Unless you are aware that you need to support very old HTTPS clients that are not supported by most sites, you can safely just transition your site to use ECDSA keys instead of RSA keys. To accomplish this if you have existing certificates managed by Certbot, you may freely change the certificate to a new private key.

If you want to use ECDSA keys for all certificates in the future, you can simply add the following line to Certbot's configuration file:

```
key-type = ecdsa
```

After this option is set, newly obtained certificates will use ECDSA keys. This includes certificates managed by Certbot that previously used RSA keys.

If you want to change a single certificate to use ECDSA keys, you'll need to issue a new Certbot command setting

```
--key-type ecdsa
```
on the command line like:

```
certbot renew --key-type ecdsa --cert-name example.com --force-renewal
```

Obtaining ECDSA certificates in addition to RSA certificates

When Certbot configures the certificates it obtains with Apache or Nginx, all HTTPS clients that we try to support can use certificates with ECDSA keys. If, however, you are aware of having a specific need to support very old TLS clients, you may want to obtain both ECDSA and RSA certificates for the same domains. Certbot can only configure Apache or Nginx to use a single certificate, however, you could manually configure your software to use the different certificates depending on your needs.

When obtaining both ECDSA and RSA certificates for the same domains with Certbot, we recommend using the

```
--cert-name
```
option to give your certificates names so that you can easily identify them. For instance, you may want to append “ecdsa” to the name of your ECDSA certificate by using a command like:

```
certbot certonly --key-type ecdsa --cert-name example.com-ecdsa
```

4.3.4 Revoking certificates

If you need to revoke a certificate, use the `revoke` subcommand to do so.

A certificate may be revoked by providing its name (see `certbot certificates`) or by providing its path directly:

```
certbot revoke --cert-name example.com
```

```
certbot revoke --cert-path /etc/letsencrypt/live/example.com/cert.pem
```

If the certificate being revoked was obtained via the `--staging`, `--test-cert` or a non-default `--server` flag, that flag must be passed to the `revoke` subcommand.

**Note:** After revocation, Certbot will (by default) ask whether you want to delete the certificate. Unless deleted, Certbot will try to renew revoked certificates the next time `certbot renew` runs.

You can also specify the reason for revoking your certificate by using the `reason` flag. Reasons include unspecified which is the default, as well as keycompromise, affiliationchanged, superseded, and cessationofoperation:
certbot revoke --cert-name example.com --reason keycompromise

**Revoking by account key or certificate private key**

By default, Certbot will try revoke the certificate using your ACME account key. If the certificate was created from the same ACME account, the revocation will be successful.

If you instead have the corresponding private key file to the certificate you wish to revoke, use `--key-path` to perform the revocation from any ACME account:

```
certbot revoke --cert-path /etc/letsencrypt/live/example.com/cert.pem --key-path /etc/letsencrypt/live/example.com/privkey.pem
```

### 4.3.5 Renewing certificates

**Note:** Let’s Encrypt CA issues short-lived certificates (90 days). Make sure you renew the certificates at least once in 3 months.

**See also:**

Most Certbot installations come with automatic renewal out of the box. See *Automated Renewals* for more details.

As of version 0.10.0, Certbot supports a `renew` action to check all installed certificates for impending expiry and attempt to renew them. The simplest form is simply:

```
certbot renew
```

This command attempts to renew any previously-obtained certificates that expire in less than 30 days. The same plugin and options that were used at the time the certificate was originally issued will be used for the renewal attempt, unless you specify other plugins or options. Unlike `certonly`, `renew` acts on multiple certificates and always takes into account whether each one is near expiry. Because of this, `renew` is suitable (and designed) for automated use, to allow your system to automatically renew each certificate when appropriate. Since `renew` only renews certificates that are near expiry it can be run as frequently as you want - since it will usually take no action.

The `renew` command includes hooks for running commands or scripts before or after a certificate is renewed. For example, if you have a single certificate obtained using the `standalone` plugin, you might need to stop the webserver before renewing so `standalone` can bind to the necessary ports, and then restart it after the plugin is finished. Example:

```
certbot renew --pre-hook "service nginx stop" --post-hook "service nginx start"
```

If a hook exits with a non-zero exit code, the error will be printed to `stderr` but renewal will be attempted anyway. A failing hook doesn’t directly cause Certbot to exit with a non-zero exit code, but since Certbot exits with a non-zero exit code when renewals fail, a failed hook causing renewal failures will indirectly result in a non-zero exit code. Hooks will only be run if a certificate is due for renewal, so you can run the above command frequently without unnecessarily stopping your webserver.

When Certbot detects that a certificate is due for renewal, `--pre-hook` and `--post-hook` hooks run before and after each attempt to renew it. If you want your hook to run only after a successful renewal, use `--deploy-hook` in a command like this:

```
certbot renew --deploy-hook /path/to/deploy-hook-script
```

You can also specify hooks by placing files in subdirectories of Certbot’s configuration directory. Assuming your configuration directory is `/etc/letsencrypt`, any executable files found in `/etc/letsencrypt/renewal-hooks/pre`, `/etc/letsencrypt/renewal-hooks/deploy`, and `/etc/letsencrypt/`
renewal-hooks/post will be run as pre, deploy, and post hooks respectively when any certificate is renewed with the renew subcommand. These hooks are run in alphabetical order and are not run for other subcommands. (The order the hooks are run is determined by the byte value of the characters in their filenames and is not dependent on your locale.)

Hooks specified in the command line, configuration file, or renewal configuration files are run as usual after running all hooks in these directories. One minor exception to this is if a hook specified elsewhere is simply the path to an executable file in the hook directory of the same type (e.g. your pre-hook is the path to an executable in /etc/letsencrypt/renewal-hooks/pre), the file is not run a second time. You can stop Certbot from automatically running executables found in these directories by including --no-directory-hooks on the command line.

More information about hooks can be found by running certbot --help renew.

If you’re sure that this command executes successfully without human intervention, you can add the command to crontab (since certificates are only renewed when they’re determined to be near expiry, the command can run on a regular basis, like every week or every day). In that case, you are likely to want to use the -q or --quiet quiet flag to silence all output except errors.

If you are manually renewing all of your certificates, the --force-renewal flag may be helpful; it causes the expiration time of the certificate(s) to be ignored when considering renewal, and attempts to renew each and every installed certificate regardless of its age. (This form is not appropriate to run daily because each certificate will be renewed every day, which will quickly run into the certificate authority rate limit.)

Note that options provided to certbot renew will apply to every certificate for which renewal is attempted; for example, certbot renew --rsa-key-size 4096 would try to replace every near-expiry certificate with an equivalent certificate using a 4096-bit RSA public key. If a certificate is successfully renewed using specified options, those options will be saved and used for future renewals of that certificate.

An alternative form that provides for more fine-grained control over the renewal process (while renewing specified certificates one at a time), is certbot certonly with the complete set of subject domains of a specific certificate specified via -d flags. You may also want to include the -n or --noninteractive flag to prevent blocking on user input (which is useful when running the command from cron).

certbot certonly -n -d example.com -d www.example.com

All of the domains covered by the certificate must be specified in this case in order to renew and replace the old certificate rather than obtaining a new one; don’t forget any www. domains! Specifying a subset of the domains creates a new, separate certificate containing only those domains, rather than replacing the original certificate. When run with a set of domains corresponding to an existing certificate, the certonly command attempts to renew that specific certificate.

Please note that the CA will send notification emails to the address you provide if you do not renew certificates that are about to expire.

Certbot is working hard to improve the renewal process, and we apologize for any inconvenience you encounter in integrating these commands into your individual environment.

**Note:** certbot renew exit status will only be 1 if a renewal attempt failed. This means certbot renew exit status will be 0 if no certificate needs to be updated. If you write a custom script and expect to run a command only after a certificate was actually renewed you will need to use the --deploy-hook since the exit status will be 0 both on successful renewal and when renewal is not necessary.
4.3.6 Modifying the Renewal Configuration File

When a certificate is issued, by default Certbot creates a renewal configuration file that tracks the options that were selected when Certbot was run. This allows Certbot to use those same options again when it comes time for renewal. These renewal configuration files are located at `/etc/letsencrypt/renewal/CERTNAME`.

For advanced certificate management tasks, it is possible to manually modify the certificate’s renewal configuration file, but this is discouraged since it can easily break Certbot’s ability to renew your certificates. If you choose to modify the renewal configuration file we advise you to test its validity with the `certbot renew --dry-run` command.

**Warning:** Modifying any files in `/etc/letsencrypt` can damage them so Certbot can no longer properly manage its certificates, and we do not recommend doing so.

For most tasks, it is safest to limit yourself to pointing symlinks at the files there, or using `--deploy-hook` to copy / make new files based upon those files, if your operational situation requires it (for instance, combining certificates and keys in different way, or having copies of things with different specific permissions that are demanded by other programs).

If the contents of `/etc/letsencrypt/archive/CERTNAME` are moved to a new folder, first specify the new folder’s name in the renewal configuration file, then run `certbot update_symlinks` to point the symlinks in `/etc/letsencrypt/live/CERTNAME` to the new folder.

If you would like the live certificate files whose symlink location Certbot updates on each run to reside in a different location, first move them to that location, then specify the full path of each of the four files in the renewal configuration file. Since the symlinks are relative links, you must follow this with an invocation of `certbot update_symlinks`.

For example, say that a certificate’s renewal configuration file previously contained the following directives:

```plaintext
archive_dir = /etc/letsencrypt/archive/example.com
cert = /etc/letsencrypt/live/example.com/cert.pem
privkey = /etc/letsencrypt/live/example.com/privkey.pem
chain = /etc/letsencrypt/live/example.com/chain.pem
fullchain = /etc/letsencrypt/live/example.com/fullchain.pem
```

The following commands could be used to specify where these files are located:

```bash
mv /etc/letsencrypt/archive/example.com /home/user/me/certbot/example_archive
sed -i 's,/etc/letsencrypt/archive/example.com,/home/user/me/certbot/example_archive,' /etc/letsencrypt/renewal/example.com.conf
mv /etc/letsencrypt/live/example.com/*.pem /home/user/me/certbot/
sed -i 's,/etc/letsencrypt/live/example.com,/home/user/me/certbot,g' /etc/letsencrypt/
        renewal/example.com.conf
certbot update_symlinks
```

4.3.7 Automated Renewals

Most Certbot installations come with automatic renewals preconfigured. This is done by means of a scheduled task which runs `certbot renew` periodically.

If you are unsure whether you need to configure automated renewal:

1. Review the instructions for your system at [https://certbot.eff.org/instructions](https://certbot.eff.org/instructions). They will describe how to set up a scheduled task, if necessary.
2. (Linux/BSD): Check your system’s crontab (typically `/etc/crontab` and `/etc/cron.*/*`) and systemd timers (`systemctl list-timers`).

### 4.4 Where are my certificates?

All generated keys and issued certificates can be found in `/etc/letsencrypt/live/$domain`, where `$domain` is the certificate name (see the note below). Rather than copying, please point your (web) server configuration directly to those files (or create symlinks). During the renewal, `/etc/letsencrypt/live` is updated with the latest necessary files.

**Note:** The certificate name `$domain` used in the path `/etc/letsencrypt/live/$domain` follows this convention:

- it is the name given to `--cert-name`,
- if `--cert-name` is not set by the user it is the first domain given to `--domains`,
- if the first domain is a wildcard domain (eg. `*.example.com`) the certificate name will be `example.com`,
- if a name collision would occur with a certificate already named `example.com`, the new certificate name will be constructed using a numerical sequence as `example.com-001`.

For historical reasons, the containing directories are created with permissions of 0700 meaning that certificates are accessible only to servers that run as the root user. If you will never downgrade to an older version of Certbot, then you can safely fix this using `chmod 0755 /etc/letsencrypt/{live,archive}`.

For servers that drop root privileges before attempting to read the private key file, you will also need to use `chgrp` and `chmod 0640` to allow the server to read `/etc/letsencrypt/live/$domain/privkey.pem`.

**Note:** `/etc/letsencrypt/archive` and `/etc/letsencrypt/keys` contain all previous keys and certificates, while `/etc/letsencrypt/live` symlinks to the latest versions.

The following files are available:

- **privkey.pem** Private key for the certificate.

  **Warning:** This must be kept secret at all times! Never share it with anyone, including Certbot developers. You cannot put it into a safe, however - your server still needs to access this file in order for SSL/TLS to work.

  **Note:** As of Certbot version 0.29.0, private keys for new certificate default to 0600. Any changes to the group mode or group owner (gid) of this file will be preserved on renewals.

  This is what Apache needs for `SSLCertificateKeyFile`, and Nginx for `ssl_certificate_key`.

- **fullchain.pem** All certificates, **including** server certificate (aka leaf certificate or end-entity certificate). The server certificate is the first one in this file, followed by any intermediates.

  This is what Apache >= 2.4.8 needs for `SSLCertificateFile`, and what Nginx needs for `ssl_certificate`.

- **cert.pem and chain.pem (less common)** cert.pem contains the server certificate by itself, and chain.pem contains the additional intermediate certificate or certificates that web browsers will need in order to validate the
server certificate. If you provide one of these files to your web server, you must provide both of them, or some browsers will show “This Connection is Untrusted” errors for your site, some of the time. 

Apache < 2.4.8 needs these for SSLCertificateFile. and SSLCertificateChainFile, respectively. 

If you’re using OCSP stapling with Nginx >= 1.3.7, chain.pem should be provided as the ssl_trusted_certificate to validate OCSP responses.

Note: All files are PEM-encoded. If you need other format, such as DER or PFX, then you could convert using openssl. You can automate that with --deploy-hook if you’re using automatic renewal.

4.5 Pre and Post Validation Hooks

Certbot allows for the specification of pre and post validation hooks when run in manual mode. The flags to specify these scripts are --manual-auth-hook and --manual-cleanup-hook respectively and can be used as follows:

```
```

This will run the authenticator.sh script, attempt the validation, and then run the cleanup.sh script. Additionally certbot will pass relevant environment variables to these scripts:

- **CERTBOT_DOMAIN**: The domain being authenticated
- **CERTBOT_VALIDATION**: The validation string
- **CERTBOT_TOKEN**: Resource name part of the HTTP-01 challenge (HTTP-01 only)
- **CERTBOT_REMAINING_CHALLENGES**: Number of challenges remaining after the current challenge
- **CERTBOT_ALL_DOMAINS**: A comma-separated list of all domains challenged for the current certificate

Additionally for cleanup:
- **CERTBOT_AUTH_OUTPUT**: Whatever the auth script wrote to stdout

Example usage for HTTP-01:

```
```

```
#!/bin/bash
echo $CERTBOT_VALIDATION > /var/www/htdocs/.well-known/acme-challenge/$CERTBOT_TOKEN
```

```
#!/bin/bash
rm -f /var/www/htdocs/.well-known/acme-challenge/$CERTBOT_TOKEN
```

Example usage for DNS-01 (Cloudflare API v4) (for example purposes only, do not use as-is)

```
certbot certonly --manual --preferred-challenges=dns --manual-auth-hook /path/to/dns/..\nauthenticator.sh --manual-cleanup-hook /path/to/dns/cleanup.sh -d secure.example.com
```

(continues on next page)

4.5. Pre and Post Validation Hooks 25
## 4.6 Changing the ACME Server

By default, Certbot uses Let's Encrypt's production server at https://acme-v02.api.letsencrypt.org/directory. You can tell Certbot to use a different CA by providing `--server` on the command line or in a configuration file with the URL of the server's ACME directory. For example, if you would like to use Let's Encrypt's staging server, you would add `--server https://acme-staging-v02.api.letsencrypt.org/directory` to the command line.

If you use `--server` to specify an ACME CA that implements the standardized version of the spec, you may be able to obtain a certificate for a wildcard domain. Some CAs (such as Let's Encrypt) require that domain validation for wildcard domains must be done through modifications to DNS records which means that the dns-01 challenge type must be used. To see a list of Certbot plugins that support this challenge type and how to use them, see [plugins](#plugins).

## 4.7 Lock Files

When processing a validation Certbot writes a number of lock files on your system to prevent multiple instances from overwriting each other’s changes. This means that by default two instances of Certbot will not be able to run in parallel.

Since the directories used by Certbot are configurable, Certbot will write a lock file for all of the directories it uses. This include Certbot's `--work-dir`, `--logs-dir`, and `--config-dir`. By default these are `/var/lib/letsencrypt`, `/var/log/letsencrypt`, and `/etc/letsencrypt` respectively. Additionally if you are using Certbot with Apache or nginx it will lock the configuration folder for that program, which are typically also in the `/etc` directory.

Note that these lock files will only prevent other instances of Certbot from using those directories, not other processes. If you’d like to run multiple instances of Certbot simultaneously you should specify different directories as the `--work-dir`, `--logs-dir`, and `--config-dir` for each instance of Certbot that you would like to run.

## 4.8 Configuration file

Certbot accepts a global configuration file that applies its options to all invocations of Certbot. Certificate specific configuration choices should be set in the `.conf` files that can be found in `/etc/letsencrypt/renewal`.

By default no cli.ini file is created (though it may exist already if you installed Certbot via a package manager, for instance). After creating one it is possible to specify the location of this configuration file with `certbot --config cli.ini` (or shorter `--c cli.ini`). An example configuration file is shown below:
# This is an example of the kind of things you can do in a configuration file.  
# All flags used by the client can be configured here. Run Certbot with  
# "--help" to learn more about the available options.  
#  
# Note that these options apply automatically to all use of Certbot for  
# obtaining or renewing certificates, so options specific to a single  
# certificate on a system with several certificates should not be placed  
# here.  

# Use ECC for the private key  
key-type = ecdsa  
ecc-curve = secp384r1  

# Use a 4096 bit RSA key instead of 2048  
rsa-key-size = 4096  

# Uncomment and update to register with the specified e-mail address  
# email = foo@example.com  

# Uncomment to use the standalone authenticator on port 443  
# authenticator = standalone  

# Uncomment to use the webroot authenticator. Replace webroot-path with the  
# path to the public_html / webroot folder being served by your web server.  
# authenticator = webroot  
# webroot-path = /usr/share/nginx/html  

# Uncomment to automatically agree to the terms of service of the ACME server  
# agree-tos = true  

# An example of using an alternate ACME server that uses EAB credentials  
# server = https://acme.sectigo.com/v2/InCommonRSAOV  
# eab-kid = somestringofstuffwithoutquotes  
# eab-hmac-key = yaddayaddahexhexnotquoted  

By default, the following locations are searched:  

- /etc/letsencrypt/cli.ini  
- $XDG_CONFIG_HOME/letsencrypt/cli.ini (or ~/.config/letsencrypt/cli.ini if  
  $XDG_CONFIG_HOME is not set).  

Since this configuration file applies to all invocations of certbot it is incorrect to list domains in it. Listing domains  
in cli.ini may prevent renewal from working. Additionally due to how arguments in cli.ini are parsed, options which  
wish to not be set should not be listed. Options set to false will instead be read as being set to true by older versions of  
Certbot, since they have been listed in the config file.
4.9 Log Rotation

By default certbot stores status logs in /var/log/letsencrypt. By default certbot will begin rotating logs once there are 1000 logs in the log directory. Meaning that once 1000 files are in /var/log/letsencrypt Certbot will delete the oldest one to make room for new logs. The number of subsequent logs can be changed by passing the desired number to the command line flag --max-log-backups.

Note: Some distributions, including Debian and Ubuntu, disable certbot’s internal log rotation in favor of a more traditional logrotate script. If you are using a distribution’s packages and want to alter the log rotation, check /etc/logrotate.d/ for a certbot rotation script.

4.10 Certbot command-line options

Certbot supports a lot of command line options. Here’s the full list, from certbot --help all:

usage:
  certbot [SUBCOMMAND] [options] [-d DOMAIN] [-d DOMAIN] ...

Certbot can obtain and install HTTPS/TLS/SSL certificates. By default, it will attempt to use a webserver both for obtaining and installing the certificate. The most common SUBCOMMANDS and flags are:

obtain, install, and renew certificates:
  (default) run Obtain & install a certificate in your current webserver
  certonly Obtain or renew a certificate, but do not install it
  renew Renew all previously obtained certificates that are near expiry
  enhance Add security enhancements to your existing configuration
  -d DOMAINS Comma-separated list of domains to obtain a certificate for

--apache Use the Apache plugin for authentication & installation
--standalone Run a standalone webserver for authentication
--nginx Use the Nginx plugin for authentication & installation
--webroot Place files in a server's webroot folder for authentication
--manual Obtain certificates interactively, or using shell script hooks

-n Run non-interactively
--test-cert Obtain a test certificate from a staging server
--dry-run Test "renew" or "certonly" without saving any certificates to disk

manage certificates:
  certificates Display information about certificates you have from Certbot
  revoke Revoke a certificate (supply --cert-name or --cert-path)
  delete Delete a certificate (supply --cert-name)

manage your account:
  register Create an ACME account
  unregister Deactivate an ACME account
  update_account Update an ACME account
  --agree-tos Agree to the ACME server's Subscriber Agreement
  -m EMAIL Email address for important account notifications

optional arguments:
  -h, --help show this help message and exit
-c CONFIG_FILE, --config CONFIG_FILE  
  path to config file (default: /etc/letsencrypt/cli.ini and ~/.config/letsencrypt/cli.ini)

-v, --verbose  
  This flag can be used multiple times to incrementally increase the verbosity of output, e.g. -vvv. (default: -2)

--max-log-backups MAX_LOG_BACKUPS  
  Specifies the maximum number of backup logs that should be kept by Certbot's built in log rotation. Setting this flag to 0 disables log rotation entirely, causing Certbot to always append to the same log file. (default: 1000)

-n, --non-interactive, --noninteractive  
  Run without ever asking for user input. This may require additional command line flags; the client will try to explain which ones are required if it finds one missing (default: False)

--force-interactive  
  Force Certbot to be interactive even if it detects it's not being run in a terminal. This flag cannot be used with the renew subcommand. (default: False)

-d DOMAIN, --domains DOMAIN, --domain DOMAIN  
  Domain names to apply. For multiple domains you can use multiple -d flags or enter a comma separated list of domains as a parameter. The first domain provided will be the subject CN of the certificate, and all domains will be Subject Alternative Names on the certificate. The first domain will also be used in some software user interfaces and as the file paths for the certificate and related material unless otherwise specified or you already have a certificate with the same name. In the case of a name collision it will append a number like 0001 to the file path name. (default: Ask)

--eab-kid EAB_KID  
  Key Identifier for External Account Binding (default: None)

--eab-hmac-key EAB_HMAC_KEY  
  HMAC key for External Account Binding (default: None)

--cert-name CERTNAME  
  Certificate name to apply. This name is used by Certbot for housekeeping and in file paths; it doesn't affect the content of the certificate itself. To see certificate names, run 'certbot certificates'. When creating a new certificate, specifies the new certificate's name. (default: the first provided domain or the name of an existing certificate on your system for the same domains)

--dry-run  
  Perform a test run of the client, obtaining test (invalid) certificates but not saving them to disk. This can currently only be used with the 'certonly' and 'renew' subcommands. Note: Although --dry-run tries to avoid making any persistent changes on a system, it is not completely side-effect free: if used with webserver authenticator plugins like apache and nginx, it makes and then reverts temporary config changes in order to obtain test certificates, and reloads webservers to deploy and then roll back those changes. It also calls --pre-hook and --post-hook commands if they are defined because they may be

(continues on next page)
necessary to accurately simulate renewal. --deploy-hook commands are not called. (default: False)

--debug-challenges
After setting up challenges, wait for user input before submitting to CA (default: False)

--preferred-chain PREFERRED_CHAIN
If the CA offers multiple certificate chains, prefer the chain whose topmost certificate was issued from this Subject Common Name. If no match, the default offered chain will be used. (default: None)

--preferred-challenges PREF_CHALLS
A sorted, comma delimited list of the preferred challenge to use during authorization with the most preferred challenge listed first (Eg, "dns" or "http,dns"). Not all plugins support all challenges. See https://certbot.eff.org/docs/using.html#plugins for details. ACME Challenges are versioned, but if you pick "http" rather than "http-01", Certbot will select the latest version automatically. (default: [])

--user-agent USER_AGENT
Set a custom user agent string for the client. User agent strings allow the CA to collect high level statistics about success rates by OS, plugin and use case, and to know when to deprecate support for past Python versions and flags. If you wish to hide this information from the Let's Encrypt server, set this to "". (default: CertbotACMEClient/1.14.0 (certbot(-auto); OS_NAME OS_VERSION) Authenticator/XXX Installer/YYY (SUBCOMMAND; flags: FLAGS) Py/major.minor.patchlevel). The flags encoded in the user agent are: --duplicate, --force-renew, --allow-subset-of-names, -n, and whether any hooks are set.

--user-agent-comment USER_AGENT_COMMENT
Add a comment to the default user agent string. May be used when repackaging Certbot or calling it from another tool to allow additional statistical data to be collected. Ignored if --user-agent is set. (Example: Foo-Wrapper/1.0) (default: None)

automation:
Flags for automating execution & other tweaks

--keep-until-expiring, --keep, --reinstall
If the requested certificate matches an existing certificate, always keep the existing one until it is due for renewal (for the 'run' subcommand this means reinstall the existing certificate). (default: Ask)

--expand
If an existing certificate is a strict subset of the requested names, always expand and replace it with the additional names. (default: Ask)

--version
show program's version number and exit

--force-renewal, --renew-by-default
If a certificate already exists for the requested domains, renew it now, regardless of whether it is near expiry. (Often --keep-until-expiring is more appropriate). Also implies --expand. (default: False)

--renew-with-new-domains
If a certificate already exists for the requested
certificate name but does not match the requested domains, renew it now, regardless of whether it is near expiry. (default: False)

```--reuse-key```
When renewing, use the same private key as the existing certificate. (default: False)

```--allow-subset-of-names```
When performing domain validation, do not consider it a failure if authorizations can not be obtained for a strict subset of the requested domains. This may be useful for allowing renewals for multiple domains to succeed even if some domains no longer point at this system. This option cannot be used with --csr. (default: False)

```--agree-tos```
Agree to the ACME Subscriber Agreement (default: Ask)

```--duplicate```
Allow making a certificate lineage that duplicates an existing one (both can be renewed in parallel) (default: False)

```-q, --quiet```
Silence all output except errors. Useful for automation via cron. Implies --non-interactive. (default: False)

### security:
Security parameters & server settings

```--rsa-key-size N```
Size of the RSA key. (default: 2048)

```--key-type {rsa,ecdsa}```
Type of generated private key (Only *ONE* per invocation can be provided at this time) (default: rsa)

```--elliptic-curve N```
The SECG elliptic curve name to use. Please see RFC 8446 for supported values. (default: secp256r1)

```--must-staple```
Adds the OCSP Must Staple extension to the certificate. Autoconfigures OCSP Stapling for supported setups (Apache version >= 2.3.3). (default: False)

```--redirect```
Automatically redirect all HTTP traffic to HTTPS for the newly authenticated vhost. (default: redirect enabled for install and run, disabled for enhance)

```--no-redirect```
Do not automatically redirect all HTTP traffic to HTTPS for the newly authenticated vhost. (default: redirect enabled for install and run, disabled for enhance)

```--hsts```
Add the Strict-Transport-Security header to every HTTP response. Forcing browser to always use SSL for the domain. Defends against SSL Stripping. (default: None)

```--uir```
Add the "Content-Security-Policy: upgrade-insecure-requests" header to every HTTP response. Forcing the browser to use https:// for every http:// resource. (default: None)

```--staple-ocsp```
Enables OCSP Stapling. A valid OCSP response is stapled to the certificate that the server offers during TLS. (default: None)

```--strict-permissions```
Require that all configuration files are owned by the current user; only needed if your config is somewhere unsafe like /tmp/ (default: False)

```--auto-hsts```
Gradually increasing max-age value for HTTP Strict Transport Security security header (default: False)
testing:
The following flags are meant for testing and integration purposes only.

--test-cert, --staging
Use the staging server to obtain or revoke test
(invalid) certificates; equivalent to --server
https://acme-staging-v02.api.letsencrypt.org/directory
(default: False)

--debug
Show tracebacks in case of errors, and allow certbot-
auto execution on experimental platforms (default: False)

--no-verify-ssl
Disable verification of the ACME server's certificate.
(default: False)

--http-01-port HTTP01_PORT
Port used in the http-01 challenge. This only affects
the port Certbot listens on. A conforming ACME server
will still attempt to connect on port 80. (default: 80)

--http-01-address HTTP01_ADDRESS
The address the server listens to during http-01
challenge. (default: )

--https-port HTTPS_PORT
Port used to serve HTTPS. This affects which port
Nginx will listen on after a LE certificate is
installed. (default: 443)

--break-my-certs
Be willing to replace or renew valid certificates with
invalid (testing/staging) certificates (default: False)

paths:
Flags for changing execution paths & servers

--cert-path CERT_PATH
Path to where certificate is saved (with certonly
--csr), installed from, or revoked (default: None)

--key-path KEY_PATH
Path to private key for certificate installation or
revocation (if account key is missing) (default: None)

--fullchain-path FULLCHAIN_PATH
Accompanying path to a full certificate chain
(certificate plus chain). (default: None)

--chain-path CHAIN_PATH
Accompanying path to a certificate chain. (default: None)

--config-dir CONFIG_DIR
Configuration directory. (default: /etc/letsencrypt)

--work-dir WORK_DIR
Working directory. (default: /var/lib/letsencrypt)

--logs-dir LOGS_DIR
Logs directory. (default: /var/log/letsencrypt)

--server SERVER
ACME Directory Resource URI. (default:
https://acme-v02.api.letsencrypt.org/directory)

manage:
Various subcommands and flags are available for managing your
certificates:
certificates
List certificates managed by Certbot
delete
Clean up all files related to a certificate

(continues on next page)
### renew
Renew all certificates (or one specified with `--cert-name`)

### revoke
Revoke a certificate specified with `--cert-path` or `--cert-name`

### update_symlinks
Recreate symlinks in your `/etc/letsencrypt/live/` directory

### run:
Options for obtaining & installing certificates

**certonly:**
Options for modifying how a certificate is obtained

---

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--csr CSR</code></td>
<td>Path to a Certificate Signing Request (CSR) in DER or PEM format. Currently <code>--csr</code> only works with the <code>certonly</code> subcommand. (default: None)</td>
</tr>
</tbody>
</table>

### renew:
The `renew` subcommand will attempt to renew all certificates (or more precisely, certificate lineages) you have previously obtained if they are close to expiry, and print a summary of the results. By default, `renew` will reuse the options used to create obtain or most recently successfully renew each certificate lineage. You can try it with `--dry-run` first. For more fine-grained control, you can renew individual lineages with the `certonly` subcommand. Hooks are available to run commands before and after renewal; see https://certbot.eff.org/docs/using.html#renewal for more information on these.

---

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--pre-hook PRE_HOOK</code></td>
<td>Command to be run in a shell before obtaining any certificates. Intended primarily for renewal, where it can be used to temporarily shut down a webserver that might conflict with the standalone plugin. This will only be called if a certificate is actually to be obtained/renewed. When renewing several certificates that have identical pre-hooks, only the first will be executed. (default: None)</td>
</tr>
<tr>
<td><code>--post-hook POST_HOOK</code></td>
<td>Command to be run in a shell after attempting to obtain/renew certificates. Can be used to deploy renewed certificates, or to restart any servers that were stopped by <code>--pre-hook</code>. This is only run if an attempt was made to obtain/renew a certificate. If multiple renewed certificates have identical post-hooks, only one will be run. (default: None)</td>
</tr>
<tr>
<td><code>--deploy-hook DEPLOY_HOOK</code></td>
<td>Command to be run in a shell once for each successfully issued certificate. For this command, the shell variable <code>$RENEWED_LINEAGE</code> will point to the config live subdirectory (for example, &quot;/etc/letsencrypt/live/example.com&quot;) containing the new certificates and keys; the shell variable <code>$RENEWED_DOMAINS</code> will contain a space-delimited list of renewed certificate domains (for example, &quot;example.com <a href="http://www.example.com">www.example.com</a>&quot;) (default: None)</td>
</tr>
<tr>
<td><code>--disable-hook-validation</code></td>
<td>Ordinarily the commands specified for <code>--pre-hook</code>/<code>--post-hook</code>/<code>--deploy-hook</code> will be checked for</td>
</tr>
</tbody>
</table>
validity, to see if the programs being run are in the $PATH, so that mistakes can be caught early, even when the hooks aren't being run just yet. The validation is rather simplistic and fails if you use more advanced shell constructs, so you can use this switch to disable it. (default: False)

```
--no-directory-hooks
```

Disable running executables found in Certbot's hook directories during renewal. (default: False)

```
--disable-renew-updates
```

Disable automatic updates to your server configuration that would otherwise be done by the selected installer plugin, and triggered when the user executes "certbot renew", regardless of if the certificate is renewed. This setting does not apply to important TLS configuration updates. (default: False)

```
--no-autorenew
```

Disable auto renewal of certificates. (default: True)

<table>
<thead>
<tr>
<th>certificates:</th>
</tr>
</thead>
<tbody>
<tr>
<td>List certificates managed by Certbot</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>delete:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Options for deleting a certificate</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>revoke:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Options for revocation of certificates</td>
</tr>
</tbody>
</table>

```
--reason {unspecified, keycompromise, affiliationchanged, superseded, cessationofoperation}
```

Specify reason for revoking certificate. (default: unspecified)

```
--delete-after-revoke
```

Delete certificates after revoking them, along with all previous and later versions of those certificates. (default: None)

```
--no-delete-after-revoke
```

Do not delete certificates after revoking them. This option should be used with caution because the 'renew' subcommand will attempt to renew undeleted revoked certificates. (default: None)

<table>
<thead>
<tr>
<th>register:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Options for account registration</td>
</tr>
</tbody>
</table>

```
--register-unsafely-without-email
```

Specifying this flag enables registering an account with no email address. This is strongly discouraged, because you will be unable to receive notice about impending expiration or revocation of your certificates or problems with your Certbot installation that will lead to failure to renew. (default: False)

```
-m EMAIL, --email EMAIL
```

Email used for registration and recovery contact. Use comma to register multiple emails, ex: u1@example.com,u2@example.com. (default: Ask).

```
--eff-email
```

Share your e-mail address with EFF (default: None)

```
--no-eff-email
```

Don't share your e-mail address with EFF (default: None)
update_account:
   Options for account modification

unregister:
   Options for account deactivation.
   --account ACCOUNT_ID Account ID to use (default: None)

install:
   Options for modifying how a certificate is deployed

rollback:
   Options for rolling back server configuration changes
   --checkpoints N Revert configuration N number of checkpoints. (default: 1)

plugins:
   Options for the "plugins" subcommand
   --init Initialize plugins. (default: False)
   --prepare Initialize and prepare plugins. (default: False)
   --authenticators Limit to authenticator plugins only. (default: None)
   --installers Limit to installer plugins only. (default: None)

update_symlinks:
   Recreates certificate and key symlinks in /etc/letsencrypt/live, if you
   changed them by hand or edited a renewal configuration file

enhance:
   Helps to harden the TLS configuration by adding security enhancements to
   already existing configuration.

plugins:
   Plugin Selection: Certbot client supports an extensible plugins
   architecture. See 'certbot plugins' for a list of all installed plugins
   and their names. You can force a particular plugin by setting options
   provided below. Running --help <plugin_name> will list flags specific to
   that plugin.

   --configurator CONFIGURATOR
   Name of the plugin that is both an authenticator and
   an installer. Should not be used together with
   --authenticator or --installer. (default: Ask)
   -a AUTHENTICATOR, --authenticator AUTHENTICATOR
   Authenticator plugin name. (default: None)
   -i INSTALLER, --installer INSTALLER
   Installer plugin name (also used to find domains).
   (default: None)
   --apache Obtain and install certificates using Apache (default: False)
   --nginx Obtain and install certificates using Nginx (default: False)
   --standalone Obtain certificates using a "standalone" webserver.
   (default: False)
--manu al  Provide laborious manual instructions for obtaining a certificate (default: False)
--webroot Obtain certificates by placing files in a webroot directory. (default: False)
--dns-cloudflare Obtain certificates using a DNS TXT record (if you are using Cloudflare for DNS). (default: False)
--dns-cloudxns Obtain certificates using a DNS TXT record (if you are using CloudXNS for DNS). (default: False)
--dns-digitalocean Obtain certificates using a DNS TXT record (if you are using DigitalOcean for DNS). (default: False)
--dns-dnssimple Obtain certificates using a DNS TXT record (if you are using DNSimple for DNS). (default: False)
--dns-dnsmadeeasy Obtain certificates using a DNS TXT record (if you are using DNS Made Easy for DNS). (default: False)
--dns-gehirn Obtain certificates using a DNS TXT record (if you are using Gehirn Infrastructure Service for DNS). (default: False)
--dns-google Obtain certificates using a DNS TXT record (if you are using Google Cloud DNS). (default: False)
--dns-linode Obtain certificates using a DNS TXT record (if you are using Linode for DNS). (default: False)
--dns-luadns Obtain certificates using a DNS TXT record (if you are using LuaDNS for DNS). (default: False)
--dns-nsone Obtain certificates using a DNS TXT record (if you are using NS1 for DNS). (default: False)
--dns-ovh Obtain certificates using a DNS TXT record (if you are using OVH for DNS). (default: False)
--dns/rfc2136 Obtain certificates using a DNS TXT record (if you are using BIND for DNS). (default: False)
--dns-route53 Obtain certificates using a DNS TXT record (if you are using Route53 for DNS). (default: False)
--dns-sakuracloud Obtain certificates using a DNS TXT record (if you are using Sakura Cloud for DNS). (default: False)

apache:
Apache Web Server plugin (Please note that the default values of the Apache plugin options change depending on the operating system Certbot is run on.)

--apache-enmod APACHE_ENMOD
Path to the Apache 'a2enmod' binary (default: None)
--apache-dismod APACHE_DISMOD
Path to the Apache 'a2dismod' binary (default: None)
--apache-le-vhost-ext APACHE_LE_VHOST_EXT
SSL vhost configuration extension (default: -le-ssl.conf)
--apache-server-root APACHE_SERVER_ROOT
Apache server root directory (default: /etc/apache2)
--apache-vhost-root APACHE_VHOST_ROOT
Apache server VirtualHost configuration root (default: None)
--apache-logs-root APACHE_LOGS_ROOT
Apache server logs directory (default: /var/log/apache2)
--apache-challenge-location APACHE_CHALLENGE_LOCATION
Directory path for challenge configuration (default: /etc/apache2)
--apache-handle-modules APACHE_HANDLE_MODULES
Let installer handle enabling required modules for you
(Only Ubuntu/Debian currently) (default: False)

--apache-handle-sites APACHE_HANDLE_SITES
Let installer handle enabling sites for you (Only
Ubuntu/Debian currently) (default: False)

--apache-ctl APACHE_CTL
Full path to Apache control script (default: apache2ctl)

--apache-bin APACHE_BIN
Full path to apache2/httpd binary (default: None)

dns-cloudflare:
Obtain certificates using a DNS TXT record (if you are using Cloudflare for DNS).

--dns-cloudflare-propagation-seconds DNS_CLOUDFLARE_PROPAGATION_SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 10)

--dns-cloudflare-credentials DNS_CLOUDFLARE_CREDENTIALS
Cloudflare credentials INI file. (default: None)

dns-cloudxns:
Obtain certificates using a DNS TXT record (if you are using CloudXNS for DNS).

--dns-cloudxns-propagation-seconds DNS_CLOUDXNS_PROPAGATION_SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 30)

--dns-cloudxns-credentials DNS_CLOUDXNS_CREDENTIALS
CloudXNS credentials INI file. (default: None)

dns-digitalocean:
Obtain certificates using a DNS TXT record (if you are using DigitalOcean for DNS).

--dns-digitalocean-propagation-seconds DNS_DIGITALOCEAN_PROPAGATION_SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 10)

--dns-digitalocean-credentials DNS_DIGITALOCEAN_CREDENTIALS
DigitalOcean credentials INI file. (default: None)

dns-dnsimple:
Obtain certificates using a DNS TXT record (if you are using DNSimple for DNS).

--dns-dnsimple-propagation-seconds DNS_DNSIMPLE_PROPAGATION_SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 30)

--dns-dnsimple-credentials DNS_DNSIMPLE_CREDENTIALS
DNSimple credentials INI file. (default: None)

dns-dnsmadeeasy:
Certbot Documentation, Release 1.15.0.dev0

(continued from previous page)

Obtain certificates using a DNS TXT record (if you are using DNS Made Easy for DNS).

--dns-dnsmadeeasy-propagation-seconds DNS_DNSMADEEASY_PROPAGATION_SECONDS
    The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 60)

--dns-dnsmadeeasy-credentials DNS_DNSMADEEASY_CREDENTIALS
    DNS Made Easy credentials INI file. (default: None)

dns-gehirn:
Obtain certificates using a DNS TXT record (if you are using Gehirn Infrastructure Service for DNS).

--dns-gehirn-propagation-seconds DNS_GEHIRN_PROPAGATION_SECONDS
    The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 30)

--dns-gehirn-credentials DNS_GEHIRN_CREDENTIALS
    Gehirn Infrastructure Service credentials file. (default: None)

dns-google:
Obtain certificates using a DNS TXT record (if you are using Google Cloud DNS for DNS).

--dns-google-propagation-seconds DNS_GOOGLE_PROPAGATION_SECONDS
    The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 60)

--dns-google-credentials DNS_GOOGLE_CREDENTIALS
    Path to Google Cloud DNS service account JSON file. 
    (See https://developers.google.com/identity/protocols/OAuth2ServiceAccount#createanaccount for information about creating a service account and 
    https://cloud.google.com/dns/access-control#permissions_and_roles for information about the required permissions.) (default: None)

dns-linode:
Obtain certificates using a DNS TXT record (if you are using Linode for DNS).

--dns-linode-propagation-seconds DNS_LINODE_PROPAGATION_SECONDS
    The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 120)

--dns-linode-credentials DNS_LINODE_CREDENTIALS
    Linode credentials INI file. (default: None)

dns-luadns:
Obtain certificates using a DNS TXT record (if you are using LuaDNS for DNS).

--dns-luadns-propagation-seconds DNS_LUADNS_PROPAGATION_SECONDS
    The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record.
record. (default: 30)
--dns-luadns-credentials DNS_LUADNS_CREDENTIALS
LuaDNS credentials INI file. (default: None)

dns-nsone:
Obtain certificates using a DNS TXT record (if you are using NS1 for DNS).

--dns-nsone-propagation-seconds DNS_NSONE_PROPAGATION SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 30)
--dns-nsone-credentials DNS_NSONE_CREDENTIALS
NS1 credentials INI file. (default: None)

dns-ovh:
Obtain certificates using a DNS TXT record (if you are using OVH for DNS).

--dns-ovh-propagation-seconds DNS_OVH_PROPAGATION SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 30)
--dns-ovh-credentials DNS_OVH_CREDENTIALS
OVH credentials INI file. (default: None)

dns-rfc2136:
Obtain certificates using a DNS TXT record (if you are using BIND for DNS).

--dns-rfc2136-propagation-seconds DNS_RFC2136_PROPAGATION SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 60)
--dns-rfc2136-credentials DNS_RFC2136_CREDENTIALS
RFC 2136 credentials INI file. (default: None)

dns-route53:
Obtain certificates using a DNS TXT record (if you are using AWS Route53 for DNS).

--dns-route53-propagation-seconds DNS_ROUTE53_PROPAGATION SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 10)

dns-sakuracloud:
Obtain certificates using a DNS TXT record (if you are using Sakura Cloud for DNS).

--dns-sakuracloud-propagation-seconds DNS_SAKURA CLOUD_PROPAGATION SECONDS
The number of seconds to wait for DNS to propagate before asking the ACME server to verify the DNS record. (default: 90)
--dns-sakuracloud-credentials DNS_SAKURA CLOUD_CREDENTIALS
Sakura Cloud credentials file. (default: None)

manual:
Authenticate through manual configuration or custom shell scripts. When
using shell scripts, an authenticator script must be provided. The environment variables available to this script depend on the type of challenge. $CERTBOT_DOMAIN will always contain the domain being authenticated. For HTTP-01 and DNS-01, $CERTBOT_VALIDATION is the validation string, and $CERTBOT_TOKEN is the filename of the resource requested when performing an HTTP-01 challenge. An additional cleanup script can also be provided and can use the additional variable $CERTBOT_AUTH_OUTPUT which contains the stdout output from the auth script. For both authenticator and cleanup script, on HTTP-01 and DNS-01 challenges, $CERTBOT_REMAINING_CHALLENGES will be equal to the number of challenges that remain after the current one, and $CERTBOT_ALL_DOMAINS contains a comma-separated list of all domains that are challenged for the current certificate.

```
--manual-auth-hook MANUAL_AUTH_HOOK
    Path or command to execute for the authentication script (default: None)
--manual-cleanup-hook MANUAL_CLEANUP_HOOK
    Path or command to execute for the cleanup script (default: None)
```

nginx:
   Nginx Web Server plugin
```
--nginx-server-root NGINX_SERVER_ROOT
    Nginx server root directory. (default: /etc/nginx or /usr/local/etc/nginx)
--nginx-ctl NGINX_CTL
    Path to the 'nginx' binary, used for 'configtest' and retrieving nginx version number. (default: nginx)
--nginx-sleep-seconds NGINX_SLEEP_SECONDS
    Number of seconds to wait for nginx configuration changes to apply when reloading. (default: 1)
```

null:
   Null Installer

standalone:
   Spin up a temporary webserver

webroot:
   Place files in webroot directory
```
--webroot-path WEBROOT_PATH, -w WEBROOT_PATH
    public_html / webroot path. This can be specified multiple times to handle different domains; each domain will have the webroot path that preceded it. For instance: "-w /var/www/example -d example.com -d www.example.com -w /var/www/thing -d thing.net -d m.thing.net" (default: Ask)
--webroot-map WEBROOT_MAP
    JSON dictionary mapping domains to webroot paths; this implies -d for each entry. You may need to escape this from your shell. E.g.: --webroot-map '!["eg1.is,m.eg1.is":/www/eg1/], "eg2.is":/www/eg2"]'
```

This option is merged with, but takes precedence over, -w / -d entries. At present, if you put webroot-map in
a config file, it needs to be on a single line, like:
webroot-map = \{"example.com":"/var/www\}. (default: 
\{\})

4.11 Getting help

If you’re having problems, we recommend posting on the Let’s Encrypt Community Forum.

If you find a bug in the software, please do report it in our issue tracker. Remember to give us as much information as possible:

- copy and paste exact command line used and the output (though mind that the latter might include some personally identifiable information, including your email and domains)
- copy and paste logs from /var/log/letsencrypt (though mind they also might contain personally identifiable information)
- copy and paste certbot --version output

- your operating system, including specific version
- specify which installation method you’ve chosen

5.1 Getting Started

Certbot has the same system requirements when set up for development. While the section below will help you install Certbot and its dependencies, Certbot needs to be run on a UNIX-like OS so if you’re using Windows, you’ll need to set up a (virtual) machine running an OS such as Linux and continue with these instructions on that UNIX-like OS.

5.1.1 Running a local copy of the client

Running the client in developer mode from your local tree is a little different than running Certbot as a user. To get set up, clone our git repository by running:

```
git clone https://github.com/certbot/certbot
```

If you’re on macOS, we recommend you skip the rest of this section and instead run Certbot in Docker. You can find instructions for how to do this here. If you’re running on Linux, you can run the following commands to install dependencies and set up a virtual environment where you can run Certbot.

Install the OS system dependencies required to run Certbot.

```
# For APT-based distributions (e.g. Debian, Ubuntu ...)
sudo apt update
sudo apt install python3-dev python3-venv gcc libaugeas0 libssl-dev \
    libffi-dev ca-certificates openssl
# For RPM-based distributions (e.g. Fedora, CentOS ...)
# NB1: old distributions will use yum instead of dnf
# NB2: RHEL-based distributions use python3X-devel instead of python3-devel (e.g. python36-devel)
sudo dnf install python3-devel gcc augeas-libs openssl-devel libffi-devel \
    redhat-rpm-config ca-certificates openssl
```

Set up the Python virtual environment that will host your Certbot local instance.

```
cd certbot
python tools/venv.py
```

**Note:** You may need to repeat this when Certbot’s dependencies change or when a new plugin is introduced.

You can now run the copy of Certbot from git either by executing `venv/bin/certbot`, or by activating the virtual environment. You can do the latter by running:

```
source venv/bin/activate
```

After running this command, `certbot` and development tools like `ipdb`, `ipython`, `pytest`, and `tox` are available in the shell where you ran the command. These tools are installed in the virtual environment and are kept separate from your global Python installation. This works by setting environment variables so the right executables are found and Python can pull in the versions of various packages needed by Certbot. More information can be found in the virtualenv docs.
5.1.2 Find issues to work on

You can find the open issues in the [github issue tracker](https://github.com/letsencrypt/certbot/issues). Comparatively easy ones are marked "good first issue". If you’re starting work on something, post a comment to let others know and seek feedback on your plan where appropriate.

Once you’ve got a working branch, you can open a pull request. All changes in your pull request must have thorough unit test coverage, pass our tests, and be compliant with the [coding style](https://github.com/letsencrypt/certbot/tree/master/docs/code_style).

5.1.3 Testing

You can test your code in several ways:

- running the *automated unit* tests,
- running the *automated integration* tests
- running an *ad hoc manual integration* test

Running automated unit tests

When you are working in a file `foo.py`, there should also be a file `foo_test.py` either in the same directory as `foo.py` or in the `tests` subdirectory (if there isn’t, make one). While you are working on your code and tests, run `python foo_test.py` to run the relevant tests.

For debugging, we recommend putting `import ipdb; ipdb.set_trace()` statements inside the source code.

Once you are done with your code changes, and the tests in `foo_test.py` pass, run all of the unit tests for Certbot and check for coverage with `tox -e py3-cover`. You should then check for code style with `tox -e lint (all files)` or `pylint --rcfile=.pylintrc path/to/file.py (single file at a time)`.

Once all of the above is successful, you may run the full test suite using `tox --skip-missing-interpreters`. We recommend running the commands above first, because running all tests like this is very slow, and the large amount of output can make it hard to find specific failures when they happen.

**Warning:** The full test suite may attempt to modify your system’s Apache config if your user has sudo permissions, so it should not be run on a production Apache server.

Running automated integration tests

Generally it is sufficient to open a pull request and let Github and Azure Pipelines run integration tests for you. However, you may want to run them locally before submitting your pull request. You need Docker and docker-compose installed and working.

The `tox environment integration` will setup Pebble, the Let’s Encrypt ACME CA server for integration testing, then launch the Certbot integration tests.

With a user allowed to access your local Docker daemon, run:

```
tox -e integration
```

Tests will be run using pytest. A test report and a code coverage report will be displayed at the end of the integration tests execution.
Running manual integration tests

You can also manually execute Certbot against a local instance of the Pebble ACME server. This is useful to verify that the modifications done to the code makes Certbot behave as expected.

To do so you need:

- Docker installed, and a user with access to the Docker client,
- an available *local copy* of Certbot.

The virtual environment set up with `python tools/venv.py` contains two CLI tools that can be used once the virtual environment is activated:

```
run_acme_server
```

- Starts a local instance of Pebble and runs in the foreground printing its logs.
- Press CTRL+C to stop this instance.
- This instance is configured to validate challenges against certbot executed locally.

**Note:** Some options are available to tweak the local ACME server. You can execute `run_acme_server --help` to see the inline help of the `run_acme_server` tool.

```
certbot_test [ARGS...]
```

- Execute certbot with the provided arguments and other arguments useful for testing purposes, such as: verbose output, full tracebacks in case Certbot crashes, *etc.*
- Execution is preconfigured to interact with the Pebble CA started with `run_acme_server`.
- Any arguments can be passed as they would be to Certbot (eg. `certbot_test certonly -d test.example.com`).

Here is a typical workflow to verify that Certbot successfully issued a certificate using an HTTP-01 challenge on a machine with Python 3:

```
python tools/venv.py
source venv/bin/activate
run_acme_server &
certbot_test certonly --standalone -d test.example.com
# To stop Pebble, launch `fg` to get back the background job, then press CTRL+C
```

Running tests in CI

Certbot uses Azure Pipelines to run continuous integration tests. If you are using our Azure setup, a branch whose name starts with `test`—will run all tests on that branch.
5.2 Code components and layout

The following components of the Certbot repository are distributed to users:

- **acme** contains all protocol specific code
- **certbot** main client code
- **certbot-apache** and **certbot-nginx** client code to configure specific web servers
- **certbot-dns-** client code to configure DNS providers
- **windows installer** Installs Certbot on Windows and is built using the files in windows-installer/

5.2.1 Plugin-architecture

Certbot has a plugin architecture to facilitate support for different webservers, other TLS servers, and operating systems. The interfaces available for plugins to implement are defined in `interfaces.py` and `plugins/common.py`.

The main two plugin interfaces are **IAuthenticator**, which implements various ways of proving domain control to a certificate authority, and **IInstaller**, which configures a server to use a certificate once it is issued. Some plugins, like the built-in Apache and Nginx plugins, implement both interfaces and perform both tasks. Others, like the built-in Standalone authenticator, implement just one interface.

There are also **IDisplay** plugins, which can change how prompts are displayed to a user.

5.2.2 Authenticators

Authenticators are plugins that prove control of a domain name by solving a challenge provided by the ACME server. ACME currently defines several types of challenges: HTTP, TLS-ALPN, and DNS, represented by classes in `acme.challenges`. An authenticator plugin should implement support for at least one challenge type.

An Authenticator indicates which challenges it supports by implementing `get_chall_pref(domain)` to return a sorted list of challenge types in preference order.

An Authenticator must also implement `perform(achalls)`, which “performs” a list of challenges by, for instance, provisioning a file on an HTTP server, or setting a TXT record in DNS. Once all challenges have succeeded or failed, Certbot will call the plugin’s `cleanup(achalls)` method to remove any files or DNS records that were needed only during authentication.

5.2.3 Installer

Installers plugins exist to actually setup the certificate in a server, possibly tweak the security configuration to make it more correct and secure (Fix some mixed content problems, turn on HSTS, redirect to HTTPS, etc). Installer plugins tell the main client about their abilities to do the latter via the `supported_enhancements()` call. We currently have two Installers in the tree, the **ApacheConfigurator**, and the **NginxConfigurator**. External projects have made some progress toward support for IIS, Icecast and Plesk.

Installers and Authenticators will oftentimes be the same class/object (because for instance both tasks can be performed by a webserver like nginx) though this is not always the case (the standalone plugin is an authenticator that listens on port 80, but it cannot install certificates; a postfix plugin would be an installer but not an authenticator).

Installers and Authenticators are kept separate because it should be possible to use the **StandaloneAuthenticator** (it sets up its own Python server to perform challenges) with a program that cannot solve challenges itself (Such as MTA installers).
5.2.4 Installer Development

There are a few existing classes that may be beneficial while developing a new `IInstaller`. Installers aimed to reconfigure UNIX servers may use Augeas for configuration parsing and can inherit from `AugeasConfigurator` class to handle much of the interface. Installers that are unable to use Augeas may still find the `Reverter` class helpful in handling configuration checkpoints and rollback.

5.2.5 Writing your own plugin

**Note:** The Certbot team is not currently accepting any new DNS plugins because we want to rethink our approach to the challenge and resolve some issues like #6464, #6503, and #6504 first.

In the meantime, you’re welcome to release it as a third-party plugin. See `certbot-dns-ispconfig` for one example of that.

Certbot client supports dynamic discovery of plugins through the `setuptools` entry points using the `certbot.plugins` group. This way you can, for example, create a custom implementation of `IAuthenticator` or the `IInstaller` without having to merge it with the core upstream source code. An example is provided in `examples/plugins/` directory.

While developing, you can install your plugin into a Certbot development virtualenv like this:

```
venv/bin/activate
pip install -e examples/plugins/
certbot_test plugins
```

Your plugin should show up in the output of the last command. If not, it was not installed properly.

Once you’ve finished your plugin and published it, you can have your users install it system-wide with `pip install`. Note that this will only work for users who have Certbot installed from OS packages or via `pip`.

Writing your own plugin snap

If you’d like your plugin to be used alongside the Certbot snap, you will also have to publish your plugin as a snap. Plugin snaps are regular confined snaps, but normally do not provide any “apps” themselves. Plugin snaps export loadable Python modules to the Certbot snap.

When the Certbot snap runs, it will use its version of Python and prefer Python modules contained in its own snap over modules contained in external snaps. This means that your snap doesn’t have to contain things like an extra copy of Python, Certbot, or their dependencies, but also that if you need a different version of a dependency than is already installed in the Certbot snap, the Certbot snap will have to be updated.

Certbot plugin snaps expose their Python modules to the Certbot snap via a `snap content interface` where `certbot-1` is the value for the `content` attribute. The Certbot snap only uses this to find the names of connected plugin snaps and it expects to find the Python modules to be loaded under `lib/python3.8/site-packages/` in the plugin snap. This location is the default when using the `core20 base snap` and the `python snapcraft` plugin.

The Certbot snap also provides a separate content interface which you can use to get metadata about the Certbot snap using the `content identifier metadata-1`.

The script used to generate the `snapcraft.yaml` files for our own externally snapped plugins can be found at `https://github.com/certbot/certbot/blob/master/tools/snap/generate_dnsplugins_snapcraft.sh`.

For more information on building externally snapped plugins, see the section on `Building the Certbot and DNS plugin snaps`.

Once you have created your own snap, if you have the snap file locally, it can be installed for use with Certbot by running:

```
snap install --classic certbot
snap set certbot trust-plugin-with-root-ok
snap install --dangerous your-snap-filename.snap
sudo snap connect certbot:plugin your-snap-name
sudo /snap/bin/certbot plugins
```

If everything worked, the last command should list your plugin in the list of plugins found by Certbot. Once your snap is published to the snap store, it will be installable through the name of the snap on the snap store without the `--dangerous` flag. If you are also using Certbot’s metadata interface, you can run `sudo snap connect your-snap-name:your-plug-name-for-metadata certbot:certbot-metadata` to connect your snap to it.

### 5.3 Coding style

Please:

1. Be consistent with the rest of the code.
3. Follow the Google Python Style Guide, with the exception that we use Sphinx-style documentation:

   ```python
def foo(arg):
      """Short description.

      :param int arg: Some number.
      :returns: Argument
      :rtype: int
      """
      return arg
   ```

4. Remember to use `pylint`.
5. You may consider installing a plugin for `editorconfig` in your editor to prevent some linting warnings.
6. Please avoid `unittest.TestCase.assertTrue` or `unittest.TestCase.assertFalse` when possible, and use `assertEqual` or more specific assert. They give better messages when it’s failing, and are generally more correct.

### 5.4 Use `certbot.compat.os` instead of `os`

Python’s standard library `os` module lacks full support for several Windows security features about file permissions (e.g. DACLs). However several files handled by Certbot (e.g. private keys) need strongly restricted access on both Linux and Windows.

To help with this, the `certbot.compat.os` module wraps the standard `os` module, and forbids usage of methods that lack support for these Windows security features.

As a developer, when working on Certbot or its plugins, you must use `certbot.compat.os` in every place you would need `os` (e.g. `from certbot.compat import os` instead of `import os`). Otherwise the tests will fail when your PR is submitted.
5.5 Mypy type annotations

Certbot uses the mypy static type checker. Python 3 natively supports official type annotations, which can then be tested for consistency using mypy. Mypy does some type checks even without type annotations; we can find bugs in Certbot even without a fully annotated codebase.

Zulip wrote a great guide to using mypy. It’s useful, but you don’t have to read the whole thing to start contributing to Certbot.

To run mypy on Certbot, use `tox -e mypy` on a machine that has Python 3 installed.

Also note that OpenSSL, which we rely on, has type definitions for crypto but not SSL. We use both. Those imports should look like this:

```python
from OpenSSL import crypto
from OpenSSL import SSL # type: ignore # https://github.com/python/typeshed/issues/2052
```

5.6 Submitting a pull request

Steps:

1. Write your code! When doing this, you should add mypy type annotations for any functions you add or modify. You can check that you’ve done this correctly by running `tox -e mypy` on a machine that has Python 3 installed.

2. Make sure your environment is set up properly and that you’re in your virtualenv. You can do this by following the instructions in the Getting Started section.

3. Run `tox -e lint` to check for pylint errors. Fix any errors.

4. Run `tox --skip-missing-interpreters` to run the entire test suite including coverage. The `--skip-missing-interpreters` argument ignores missing versions of Python needed for running the tests. Fix any errors.

5. If any documentation should be added or updated as part of the changes you have made, please include the documentation changes in your PR.

6. Submit the PR. Once your PR is open, please do not force push to the branch containing your pull request to squash or amend commits. We use squash merges on PRs and rewriting commits makes changes harder to track between reviews.

7. Did your tests pass on Azure Pipelines? If they didn’t, fix any errors.

5.7 Asking for help

If you have any questions while working on a Certbot issue, don’t hesitate to ask for help! You can do this in the Certbot channel in EFF’s Mattermost instance for its open source projects as described below.

You can get involved with several of EFF’s software projects such as Certbot at the EFF Open Source Contributor Chat Platform. By signing up for the EFF Open Source Contributor Chat Platform, you consent to share your personal information with the Electronic Frontier Foundation, which is the operator and data controller for this platform. The channels will be available both to EFF, and to other users of EFFOSCCP, who may use or disclose information in these channels outside of EFFOSCCP. EFF will use your information, according to the Privacy Policy, to further the mission of EFF, including hosting and moderating the discussions on this platform.
Use of EFFOSCCP is subject to the EFF Code of Conduct. When investigating an alleged Code of Conduct violation, EFF may review discussion channels or direct messages.

### 5.8 Building the Certbot and DNS plugin snaps

Instructions for how to manually build and run the Certbot snap and the externally snapped DNS plugins that the Certbot project supplies are located in the README file at https://github.com/certbot/certbot/tree/master/tools/snap.

### 5.9 Updating the documentation

Many of the packages in the Certbot repository have documentation in a docs/ directory. This directory is located under the top level directory for the package. For instance, Certbot’s documentation is under certbot/docs.

To build the documentation of a package, make sure you have followed the instructions to set up a local copy of Certbot including activating the virtual environment. After that, cd to the docs directory you want to build and run the command:

```
make clean html
```

This would generate the HTML documentation in _build/html in your current docs/ directory.

### 5.10 Running the client with Docker

You can use Docker Compose to quickly set up an environment for running and testing Certbot. To install Docker Compose, follow the instructions at https://docs.docker.com/compose/install/.

**Note:** Linux users can simply run `pip install docker-compose` to get Docker Compose after installing Docker Engine and activating your shell as described in the Getting Started section.

Now you can develop on your host machine, but run Certbot and test your changes in Docker. When using docker-compose make sure you are inside your clone of the Certbot repository. As an example, you can run the following command to check for linting errors:

```
docker-compose run --rm --service-ports development bash -c 'tox -e lint'
```

You can also leave a terminal open running a shell in the Docker container and modify Certbot code in another window. The Certbot repo on your host machine is mounted inside of the container so any changes you make immediately take effect. To do this, run:

```
docker-compose run --rm --service-ports development bash
```

Now running the check for linting errors described above is as easy as:

```
tox -e lint
```
6.1 Releases

We release packages and upload them to PyPI (wheels and source tarballs).

- https://pypi.python.org/pypi/acme
- https://pypi.python.org/pypi/certbot
- https://pypi.python.org/pypi/certbot-apache
- https://pypi.python.org/pypi/certbot-nginx
- https://pypi.python.org/pypi/certbot-dns-cloudflare
- https://pypi.python.org/pypi/certbot-dns-cloudxns
- https://pypi.python.org/pypi/certbot-dns-digitalocean
- https://pypi.python.org/pypi/certbot-dns-dnsimple
- https://pypi.python.org/pypi/certbot-dns-dnsmadeeasy
- https://pypi.python.org/pypi/certbot-dns-google
- https://pypi.python.org/pypi/certbot-dns-linode
- https://pypi.python.org/pypi/certbot-dns-luadns
- https://pypi.python.org/pypi/certbot-dns-nsone
- https://pypi.python.org/pypi/certbot-dns-ovh
- https://pypi.python.org/pypi/certbot-dns-rfc2136
- https://pypi.python.org/pypi/certbot-dns-route53

The following scripts are used in the process:

We use git tags to identify releases, using Semantic Versioning. For example: v0.11.1.

Our packages are cryptographically signed and their signature can be verified using the PGP key A2CFB51FA275A7286234E7B24D17C995CD9775F2. This key can be found on major key servers and at https://dl.eff.org/certbot.pub.
6.2 Notes for package maintainers

0. Please use our tagged releases, not master!

1. Do not package certbot-compatibility-test as it’s only used internally.

2. To run tests on our packages, you should use pytest by running the command python -m pytest. Running pytest directly may not work because PYTHONPATH is not handled the same way and local modules may not be found by the test runner.

3. If you’d like to include automated renewal in your package:
   - certbot renew -q should be added to crontab or systemd timer.
   - A random per-machine time offset should be included to avoid having a large number of your clients hit Let’s Encrypt’s servers simultaneously.
   - --preconfigured-renewal should be included on the CLI or in cli.ini for all invocations of Certbot, so that it can adjust its interactive output regarding automated renewal (Certbot >= 1.9.0).

4. jws is an internal script for acme module and it doesn’t have to be packaged - it’s mostly for debugging: you can use it as echo foo | jws sign | jws verify.

5. Do get in touch with us. We are happy to make any changes that will make packaging easier. If you need to apply some patches don’t do it downstream - make a PR here.
All Certbot components including acme, Certbot, and non-third party plugins follow Semantic Versioning both for its Python API and for the application itself. This means that we will not change behavior in a backwards incompatible way except in a new major version of the project.

Note: None of this applies to the behavior of Certbot distribution mechanisms such as our snaps or OS packages whose behavior may change at any time. Semantic versioning only applies to the common Certbot components that are installed by various distribution methods.

For Certbot as an application, the command line interface and non-interactive behavior can be considered stable with two exceptions. The first is that no aspects of Certbot’s console or log output should be considered stable and it may change at any time. The second is that Certbot’s behavior should only be considered stable with certain files but not all. Files with which users should expect Certbot to maintain its current behavior with are:

- `/etc/letsencrypt/live/$domain/{cert,chain,fullchain,privkey}.pem`, where $domain is the certificate name (see Where are my certificates? for more details)
- CLI configuration files
- Hook directories in `/etc/letsencrypt/renewal-hooks`

Certbot’s behavior with other files may change at any point.

Another area where Certbot should not be considered stable is its behavior when not run in non-interactive mode which also may change at any point.

In general, if we’re making a change that we expect will break some users, we will bump the major version and will have warned about it in a prior release when possible. For our Python API, we will issue warnings using Python’s warning module. For application level changes, we will print and log warning messages.

9.1 certbot package

Certbot client.

9.1.1 Subpackages

certbot.compat package

Compatibility layer to run certbot both on Linux and Windows.
This package contains all logic that needs to be implemented specifically for Linux and for Windows. Then the rest of
certbot code relies on this module to be platform agnostic.

Submodules

certbot.compat.filesystem module

Compat module to handle files security on Windows and Linux

certbot.compat.filesystem.chomp(file_path: str, mode: int) → None
Apply a POSIX mode on given file_path:
• for Linux, the POSIX mode will be directly applied using chmod,
• for Windows, the POSIX mode will be translated into a Windows DACL that make sense for Certbot
context, and applied to the file using kernel calls.

The definition of the Windows DACL that correspond to a POSIX mode, in the context of Certbot,
is explained at https://github.com/certbot/certbot/issues/6356 and is implemented by the method
_generate_windows_flags().

Parameters
• file_path (str) – Path of the file
• mode (int) – POSIX mode to apply

certbot.compat.filesystem.umask(mask: int) → int
Set the current numeric umask and return the previous umask. On Linux, the built-in umask method is used. On
Windows, our Certbot-side implementation is used.

Parameters mask (int) – The user file-creation mode mask to apply.
Return type  int

Returns  The previous umask value.

certbot.compat.filesystem.copy_ownership_and_apply_mode(src: str, dst: str, mode: int, copy_user: bool, copy_group: bool) → None

Copy ownership (user and optionally group on Linux) from the source to the destination, then apply given mode in compatible way for Linux and Windows. This replaces the os.chown command.

Parameters

• **src** (str) – Path of the source file
• **dst** (str) – Path of the destination file
• **mode** (int) – Permission mode to apply on the destination file
• **copy_user** (bool) – Copy user if True
• **copy_group** (bool) – Copy group if True on Linux (has no effect on Windows)

certbot.compat.filesystem.copy_ownership_and_mode(src: str, dst: str, copy_user: bool = True, copy_group: bool = True) → None

Copy ownership (user and optionally group on Linux) and mode/DACL from the source to the destination.

Parameters

• **src** (str) – Path of the source file
• **dst** (str) – Path of the destination file
• **copy_user** (bool) – Copy user if True
• **copy_group** (bool) – Copy group if True on Linux (has no effect on Windows)

certbot.compat.filesystem.check_mode(file_path: str, mode: int) → bool

Check if the given mode matches the permissions of the given file. On Linux, will make a direct comparison, on Windows, mode will be compared against the security model.

Parameters

• **file_path** (str) – Path of the file
• **mode** (int) – POSIX mode to test

Return type  bool

Returns  True if the POSIX mode matches the file permissions

certbot.compat.filesystem.check_owner(file_path: str) → bool

Check if given file is owned by current user.

Parameters  **file_path** (str) – File path to check

Return type  bool

Returns  True if given file is owned by current user, False otherwise.

certbot.compat.filesystem.check_permissions(file_path: str, mode: int) → bool

Check if given file has the given mode and is owned by current user.

Parameters

• **file_path** (str) – File path to check
• **mode** (int) – POSIX mode to check
Return type: bool

Returns: True if file has correct mode and owner, False otherwise.

certbot.compat.filesystem.open (file_path: str, flags: int, mode: int = 511) → int

Wrapper of original os.open function, that will ensure on Windows that given mode is correctly applied.

Parameters:
- **file_path (str)** – The file path to open
- **flags (int)** – Flags to apply on file while opened
- **mode (int)** – POSIX mode to apply on file when opened, Python defaults will be applied if None

Returns: the file descriptor to the opened file

Return type: int

Raise: OSErrord(errno.EEXIST) if the file already exists and os.O_CREAT & os.O_EXCL are set, OSErrord(errno.EACCES) on Windows if the file already exists and is a directory, and os.O_CREAT is set.

certbot.compat.filesystem.makedirs (file_path: str, mode: int = 511) → None

Rewrite of original os.makedirs function, that will ensure on Windows that given mode is correctly applied.

Parameters:
- **file_path (str)** – The file path to open
- **mode (int)** – POSIX mode to apply on leaf directory when created, Python defaults will be applied if None

certbot_compat.filesystem.mkdir (file_path: str, mode: int = 511) → None

Rewrite of original os.mkdir function, that will ensure on Windows that given mode is correctly applied.

Parameters:
- **file_path (str)** – The file path to open
- **mode (int)** – POSIX mode to apply on directory when created, Python defaults will be applied if None

certbot_compat.filesystem.replace (src: str, dst: str) → None

Rename a file to a destination path and handles situations where the destination exists.

Parameters:
- **src (str)** – The current file path.
- **dst (str)** – The new file path.

certbot_compat.filesystem.realpath (file_path: str) → str

Find the real path for the given path. This method resolves symlinks, including recursive symlinks, and is protected against symlinks that creates an infinite loop.

Parameters: **file_path (str)** – The path to resolve

Returns: The real path for the given path

Return type: str

certbot_compat.filesystem.readlink (link_path: str) → str

Return a string representing the path to which the symbolic link points.

Parameters: **link_path (str)** – The symlink path to resolve
Returns The path the symlink points to

Returns str

Raise ValueError if a long path (260> characters) is encountered on Windows
certbot.compat.filesystem.is_executable(path: str) → bool
Is path an executable file?
Parameters path (str) – path to test
Returns True if path is an executable file
Return type bool
certbot.compat.filesystem.has_world_permissions(path: str) → bool
Check if everybody/world has any right (read/write/execute) on a file given its path.
Parameters path (str) – path to test
Returns True if everybody/world has any right to the file
Return type bool
certbot.compat.filesystem.compute_private_key_mode(old_key: str, base_mode: int) → int
Calculate the POSIX mode to apply to a private key given the previous private key.
Parameters
• old_key (str) – path to the previous private key
• base_mode (int) – the minimum modes to apply to a private key
Returns the POSIX mode to apply
Return type int
certbot.compat.filesystem.has_same_ownership(path1: str, path2: str) → bool
Return True if the ownership of two files given their respective path is the same. On Windows, ownership is checked against owner only, since files do not have a group owner.
Parameters
• path1 (str) – path to the first file
• path2 (str) – path to the second file
Returns True if both files have the same ownership, False otherwise
Return type bool
certbot.compat.filesystem.has_min_permissions(path: str, min_mode: int) → bool
Check if a file given its path has at least the permissions defined by the given minimal mode. On Windows, group permissions are ignored since files do not have a group owner.
Parameters
• path (str) – path to the file to check
• min_mode (int) – the minimal permissions expected
Returns True if the file matches the minimal permissions expectations, False otherwise
Return type bool
certbot.compat.misc module

This compat module handles various platform specific calls that do not fall into one particular category.

certbot.compat.misc.raise_for_non_administrative_windows_rights() \(\rightarrow\) None

On Windows, raise if current shell does not have the administrative rights. Do nothing on Linux.

Raises errors.Error – If the current shell does not have administrative rights on Windows.

certbot.compat.misc.readline_with_timeout(timeout: float, prompt: str) \(\rightarrow\) str

Read user input to return the first line entered, or raise after specified timeout.

Parameters

• timeout (float) – The timeout in seconds given to the user.

• prompt (str) – The prompt message to display to the user.

Returns The first line entered by the user.

Return type str

certbot.compat.misc.get_default_folder(folder_type: str) \(\rightarrow\) str

Return the relevant default folder for the current OS

Parameters folder_type (str) – The type of folder to retrieve (config, work or logs)

Returns The relevant default folder.

Return type str

certbot.compat.misc.underscores_for_unsupported_characters_in_path(path: str) \(\rightarrow\) str

Replace unsupported characters in path for current OS by underscores.

:param str path: the path to normalize
:return: the normalized path
:rtype: str

certbot.compat.misc.execute_command(cmd_name: str, shell_cmd: str, env: Optional[dict] = None) \(\rightarrow\) Tuple[str, str]

Run a command:

• on Linux command will be run by the standard shell selected with Popen(shell=True)

• on Windows command will be run in a Powershell shell

Parameters

• cmd_name (str) – the user facing name of the hook being run

• shell_cmd (str) – shell command to execute

• env (dict) – environ to pass into Popen

Returns tuple (str stderr, str stdout)
certbot.compat.os module

This compat modules is a wrapper of the core os module that forbids usage of specific operations (e.g. chown, chmod, getuid) that would be harmful to the Windows file security model of Certbot. This module is intended to replace standard os module throughout certbot projects (except acme).

This module has the same API as the os module in the Python standard library except for the functions defined below.

isort:skip_file
certbot.compat.os.\texttt{access}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.access() is forbidden

certbot.compat.os.\texttt{chmod}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.chmod() is forbidden

certbot.compat.os.\texttt{chown}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.chown() is forbidden

certbot.compat.os.\texttt{fstat}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.stat() is forbidden

certbot.compat.os.\texttt{mkdir}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.mkdir() is forbidden

certbot.compat.os.\texttt{open}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.open() is forbidden

certbot.compat.os.\texttt{rename}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.rename() is forbidden

certbot.compat.os.\texttt{replace}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.replace() is forbidden

certbot.compat.os.\texttt{stat}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.stat() is forbidden

certbot.compat.os.\texttt{umask}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.chmod() is forbidden

certbot.compat.os.\texttt{makedirs}(*\texttt{unused\_args}, **\texttt{unused\_kwargs})
    Method os.makedirs() is forbidden

certbot.display package

Certbot display utilities.

Submodules

certbot.display.ops module

Contains UI methods for LE user operations.

certbot.display.ops.\texttt{get\_email}(\texttt{invalid=False}, \texttt{optional=True})
    Prompt for valid email address.

    Parameters

    - \texttt{invalid}(bool) – True if an invalid address was provided by the user
• **optional** *(bool)* – True if the user can use –register-un Safely-without-email to avoid providing an e-mail

Returns e-mail address

Return type **str**

Raises **errors.Error** – if the user cancels

```python
certbot.display.ops.choose_account(accounts)
```

Choose an account.

**Parameters**

accounts *(list)* – Containing at least one Account

```python
certbot.display.ops.choose_values(values, question=None)
```

Display screen to let user pick one or multiple values from the provided list.

**Parameters**

values *(list)* – Values to select from

Returns List of selected values

Return type **list**

```python
certbot.display.ops.choose_names(installer, question=None)
```

Display screen to select domains to validate.

**Parameters**

• installer *(certbot.interfaces.IInstaller)* – An installer object

• question *(str)* – Overriding default question to ask the user if asked to choose from domain names.

Returns List of selected names

Return type **list** of **str**

```python
certbot.display.ops.get_valid_domains(domains)
```

Helper method for choose_names that implements basic checks on domain names

**Parameters**

domains *(list)* – Domain names to validate

Returns List of valid domains

Return type **list**

```python
certbot.display.ops.success_installation(domains)
```

Display a box confirming the installation of HTTPS.

**Parameters**

domains *(list)* – domain names which were enabled

```python
certbot.display.ops.success_renewal(domains)
```

Display a box confirming the renewal of an existing certificate.

**Parameters**

domains *(list)* – domain names which were renewed

```python
certbot.display.ops.success_revocation(cert_path)
```

Display a message confirming a certificate has been revoked.

**Parameters**

cert_path *(list)* – path to certificate which was revoked.

```python
certbot.display.ops.validated_input validator, *args, **kwargs
```

Like **input**, but with validation.

**Parameters**

---

9.1. certbot package 65
- **validator** (*callable*) – A method which will be called on the supplied input. If the method raises an `errors.Error`, its text will be displayed and the user will be re-prompted.
- ***args** (*list*) – Arguments to be passed to `input`.
- ****kwargs (**dict**) – Arguments to be passed to `input`.

**Returns** as `input`  
**Return type** tuple

`certbot.display.ops.validated_directory`(*validator*, *args*, **kwargs*)  
Like `directory_select`, but with validation.

**Parameters**
- **validator** (*callable*) – A method which will be called on the supplied input. If the method raises an `errors.Error`, its text will be displayed and the user will be re-prompted.
- ***args** (*list*) – Arguments to be passed to `directory_select`.
- ****kwargs (**dict**) – Arguments to be passed to `directory_select`.

**Returns** as `directory_select`  
**Return type** tuple

**certbot.display.util module**

Certbot display.

This module (`certbot.display.util`) or its companion `certbot.display.ops` should be used whenever:

- Displaying status information to the user on the terminal
- Collecting information from the user via prompts

Other messages can use the `logging` module. See `log.py`.

`certbot.display.util.OK = 'ok'`  
Display exit code indicating user acceptance.

`certbot.display.util.CANCEL = 'cancel'`  
Display exit code for a user canceling the display.

`certbot.display.util.HELP = 'help'`  
Display exit code when for when the user requests more help. (UNUSED)

`certbot.display.util.ESC = 'esc'`  
Display exit code when the user hits Escape (UNUSED)

`certbot.display.util.SIDE_FRAME = '-----'`  
Display boundary (alters spaces, so when copy-pasted, markdown doesn’t interpret it as a heading)

`certbot.display.util.input_with_timeout (prompt=None, timeout=36000.0)`  
Get user input with a timeout.

Behaves the same as the built-in `input`, however, an error is raised if a user doesn’t answer after timeout seconds. The default timeout value was chosen to place it just under 12 hours for users following our advice and running Certbot twice a day.

**Parameters**
• **prompt** (*str*) – prompt to provide for input

• **timeout** (*float*) – maximum number of seconds to wait for input

Returns user response

Return type *str*

:raises errors.Error if no answer is given before the timeout

```python
certbot.display.util.notify(msg: str) → None
```
Display a basic status message.

Parameters

• **msg** (*str*) – message to display

```python
class certbot.display.util.FileDisplay(outfile, force_interactive)
```
File-based display.

```python
notification(message, pause=True, wrap=True, force_interactive=False, decorate=True)
```
Displays a notification and waits for user acceptance.

Parameters

• **message** (*str*) – Message to display

• **pause** (*bool*) – Whether or not the program should pause for the user’s confirmation

• **wrap** (*bool*) – Whether or not the application should wrap text

• **force_interactive** (*bool*) – True if it’s safe to prompt the user because it won’t cause any workflow regressions

• **decorate** (*bool*) – Whether to surround the message with a decorated frame

```python
menu(message, choices, ok_label=None, cancel_label=None, help_label=None, default=None, cli_flag=None, force_interactive=False, **unused_kwargs)
```
Display a menu.

Parameters

• **message** (*str*) – title of menu

• **choices** (*list of tuples (tag, item) or list of descriptions tags will be enumerated*) – Menu lines, len must be > 0

• **default** – default value to return (if one exists)

• **cli_flag** (*str*) – option used to set this value with the CLI

• **force_interactive** (*bool*) – True if it’s safe to prompt the user because it won’t cause any workflow regressions

Returns tuple of (**code**, **index**) where **code** - str display exit code **index** - int index of the user’s selection

Return type *tuple*

```python
input(message, default=None, cli_flag=None, force_interactive=False, **unused_kwargs)
```
Accept input from the user.

Parameters

• **message** (*str*) – message to display to the user

• **default** – default value to return (if one exists)

• **cli_flag** (*str*) – option used to set this value with the CLI
- **force_interactive** *(bool)* – True if it’s safe to prompt the user because it won’t cause any workflow regressions

Returns tuple of *(code, input)* where *code* - str display exit code *input* - str of the user’s input

Return type tuple

**yesno** *(message, yes_label='Yes', no_label='No', default=None, cli_flag=None, force_interactive=False, **unused_kwargs)*

Query the user with a yes/no question.

Yes and No label must begin with different letters, and must contain at least one letter each.

Parameters

- **message** *(str)* – question for the user
- **yes_label** *(str)* – Label of the “Yes” parameter
- **no_label** *(str)* – Label of the “No” parameter
- **default** – default value to return (if one exists)
- **cli_flag** *(str)* – option used to set this value with the CLI
- **force_interactive** *(bool)* – True if it’s safe to prompt the user because it won’t cause any workflow regressions

Returns True for “Yes”, False for “No”

Return type bool

**checklist** *(message, tags, default=None, cli_flag=None, force_interactive=False, **unused_kwargs)*

Display a checklist.

Parameters

- **message** *(str)* – Message to display to user
- **tags** *(list)* – str tags to select, len(tags) > 0
- **default** – default value to return (if one exists)
- **cli_flag** *(str)* – option used to set this value with the CLI
- **force_interactive** *(bool)* – True if it’s safe to prompt the user because it won’t cause any workflow regressions

Returns tuple of *(code, tags)* where *code* - str display exit code *tags* - list of selected tags

Return type tuple

**directory_select** *(message, default=None, cli_flag=None, force_interactive=False, **unused_kwargs)*

Display a directory selection screen.

Parameters

- **message** *(str)* – prompt to give the user
- **default** – default value to return (if one exists)
- **cli_flag** *(str)* – option used to set this value with the CLI
- **force_interactive** *(bool)* – True if it’s safe to prompt the user because it won’t cause any workflow regressions
Returns tuple of the form (code, string) where code - display exit code string - input entered by the user

certbot.display.util.assert_valid_call (prompt, default, cli_flag, force_interactive)
Verify that provided arguments is a valid IDisplay call.

Parameters

• prompt (str) – prompt for the user
• default – default answer to prompt
• cli_flag (str) – command line option for setting an answer to this question
• force_interactive (bool) – if interactivity is forced by the IDisplay call

class certbot.display.util.NoninteractiveDisplay (outfile, *unused_args, **unused_kwargs)
Bases: object
An iDisplay implementation that never asks for interactive user input

notification (message, pause=False, wrap=True, decorate=True, **unused_kwargs)
Displays a notification without waiting for user acceptance.

Parameters

• message (str) – Message to display to stdout
• pause (bool) – The NoninteractiveDisplay waits for no keyboard
• wrap (bool) – Whether or not the application should wrap text
• decorate (bool) – Whether to apply a decorated frame to the message

menu (message, choices, ok_label=None, cancel_label=None, help_label=None, default=None, cli_flag=None, **unused_kwargs)
Avoid displaying a menu.

Parameters

• message (str) – title of menu
• choices (list of tuples (tag, item) or list of descriptions (tags will be enumerated)) – Menu lines, len must be > 0
• default (int) – the default choice
• kwargs (dict) – absorbs various irrelevant labelling arguments

Returns tuple of (code, index) where code - str display exit code index - int index of the user’s selection

Return type tuple

Raises errors.MissingCommandlineFlag – if there was no default

input (message, default=None, cli_flag=None, **unused_kwargs)
Accept input from the user.

Parameters message (str) – message to display to the user

Returns tuple of (code, input) where code - str display exit code input - str of the user’s input

Return type tuple

Raises errors.MissingCommandlineFlag – if there was no default
**yesno** *(message, yes_label=None, no_label=None, default=None, cli_flag=None, **unused_kwargs)*

Decide Yes or No, without asking anybody

**Parameters**

- **message** (*str*) – question for the user
- **kwargs** (*dict*) – absorbs yes_label, no_label

**Raises** `errors.MissingCommandlineFlag` – if there was no default

**Returns** True for “Yes”, False for “No”

**Return type** `bool`

**checklist** *(message, tags, default=None, cli_flag=None, **unused_kwargs)*

Display a checklist.

**Parameters**

- **message** (*str*) – Message to display to user
- **tags** (*list*) – str tags to select, len(tags) > 0
- **kwargs** (*dict*) – absorbs default_status arg

**Returns** tuple of (*code*, *tags*) where

- **code** – str display exit code
- **tags** – list of selected tags

**Return type** `tuple`

**directory_select** *(message, default=None, cli_flag=None, **unused_kwargs)*

Simulate prompting the user for a directory.

This function returns default if it is not `None`, otherwise, an exception is raised explaining the problem. If cli_flag is not `None`, the error message will include the flag that can be used to set this value with the CLI.

**Parameters**

- **message** (*str*) – prompt to give the user
- **default** – default value to return (if one exists)
- **cli_flag** (*str*) – option used to set this value with the CLI

**Returns** tuple of the form (*code*, *string*) where

- **code** – int display exit code
- **string** – input entered by the user

**certbot.display.util.separate_list_input** *(input_)*

Separate a comma or space separated list.

**Parameters** **input** (*str*) – input from the user

**Returns** strings

**Return type** `list`

**certbot.display.util.summarize_domain_list** *(domains: List[str]) → str*

Summarizes a list of domains in the format of: example.com.com and N more domains

or if there is are only two domains: example.com and www.example.com

or if there is only one domain: example.com

**Parameters** **domains** (*list*) – str list of domains

**Returns** the domain list summary

**Return type** `str`
certbot.plugins package

Certbot plugins.

Submodules

certbot.plugins.common module

Plugin common functions.

certbot.plugins.common.option_namespace(name)
   ArgumentParser options namespace (prefix of all options).

certbot.plugins.common.dest_namespace(name)
   ArgumentParser dest namespace (prefix of all destinations).

class certbot.plugins.common.Plugin(config, name)
   Bases: object
   Generic plugin.
      abstract classmethod add_parser_arguments(add)
         Add plugin arguments to the CLI argument parser.
            Parameters
            add (callable) – Function that proxies calls to argparse.
               ArgumentParser.add_argument prepending options with unique plugin name prefix.

classmethod inject_parser_options(parser, name)
   Inject parser options.
      See inject_parser_options for docs.

property option_namespace
   ArgumentParser options namespace (prefix of all options).

property option_name(name)
   Option name (include plugin namespace).

property dest_namespace
   ArgumentParser dest namespace (prefix of all destinations).

dest(var)
   Find a destination for given variable var.

conf(var)
   Find a configuration value for variable var.

class certbot.plugins.common.Installer(*args, **kwargs)
   Bases: certbot.plugins.common.Plugin
   An installer base class with reverter and ssl_dhparam methods defined.
   Installer plugins do not have to inherit from this class.
   add_to_checkpoint(save_files, save_notes, temporary=False)
      Add files to a checkpoint.

      Parameters
         • save_files(set) – set of filepaths to save
         • save_notes(str) – notes about changes during the save
• **temporary** *(bool) – True if the files should be added to a temporary checkpoint rather than a permanent one. This is usually used for changes that will soon be reverted.*

**Raises** **errors.PluginError** – when unable to add to checkpoint

**finalize_checkpoint** *(title)*

Timestamp and save changes made through the reverter.

**Parameters** **title** *(str)* – Title describing checkpoint

**Raises** **errors.PluginError** – when an error occurs

**recovery_routine** *

Revert all previously modified files.

Reverts all modified files that have not been saved as a checkpoint

**Raises** **errors.PluginError** – If unable to recover the configuration

**revert_temporary_config** *

Rollback temporary checkpoint.

**Raises** **errors.PluginError** – when unable to revert config

**rollback_checkpoints** *(rollback=1)*

Rollback saved checkpoints.

**Parameters** **rollback** *(int)* – Number of checkpoints to revert

**Raises** **errors.PluginError** – If there is a problem with the input or the function is unable to correctly revert the configuration

**property ssl_dhparams**

Full absolute path to ssl_dhparams file.

**property updated_ssl_dhparams_digest**

Full absolute path to digest of updated ssl_dhparams file.

**install_ssl_dhparams** *

Copy Certbot’s ssl_dhparams file into the system’s config dir if required.

**class** **certbot.plugins.common.Addr** *(tup, ipv6=False)*

**Bases:** **object**

Represents an virtual host address.

**Parameters**

• **addr** *(str)* – addr part of vhost address

• **port** *(str)* – port number or *, or “”

**classmethod** **fromstring** *(str_addr)*

Initialize Addr from string.

**normalized_tuple** *

Normalized representation of addr/port tuple

**get_addr** *

Return addr part of Addr object.

**get_port** *

Return port.

**get_addr_obj** *(port)*

Return new address object with same addr and new port.
get_ipv6_exploded()
Return IPv6 in normalized form

class certbot.plugins.common.ChallengePerformer(configurator)
Bases: object
Abstract base for challenge performers.

Variables
• configurator – Authenticator and installer plugin
• achalls(list of KeyAuthorizationAnnotatedChallenge) – Annotated challenges
• indices(list of int) – Holds the indices of challenges from a larger array so the user of the class doesn’t have to.

add_chall(achall, idx=None)
Store challenge to be performed when perform() is called.

Parameters
• achall(KeyAuthorizationAnnotatedChallenge) – Annotated challenge.
• idx(int) – index to challenge in a larger array

perform()
Perform all added challenges.

Returns challenge responses
Return type list of acme.challenges.KeyAuthorizationChallengeResponse

certbot.plugins.common.install_version_controlled_file(dest_path, digest_path, src_path, all_hashes)
Copy a file into an active location (likely the system’s config dir) if required.

Parameters
• dest_path(str) – destination path for version controlled file
• digest_path(str) – path to save a digest of the file in
• src_path(str) – path to version controlled file found in distribution
• all_hashes(list) – hashes of every released version of the file

certbot.plugins.common.dir_setup(test_dir, pkg)
Setup the directories necessary for the configurator.

certbot.plugins.dns_common module

Common code for DNS Authenticator Plugins.

class certbot.plugins.dns_common.DNSAuthenticator(config, name)
Bases: certbot.plugins.common.Plugin
Base class for DNS Authenticators

classmethod add_parser_arguments(add, default_propagation_seconds=10)
Add plugin arguments to the CLI argument parser.
Parameters `add` *(callable)* — Function that proxies calls to `argparse. ArgumentParser.add_argument` prepending options with unique plugin name prefix.

```python
def get_chall_pref(unused_domain)
def prepare()
def more_info() -> str
def perform(achalls)
def cleanup(achalls)
```

```python
class certbot.plugins.dns_common.CredentialsConfiguration(filename, mapper=<function CredentialsConfiguration.<lambda>>)
```

Bases: `object`

Represents a user-supplied file which stores API credentials.

```python
def require(required_variables)
    Ensures that the supplied set of variables are all present in the file.
    Parameters `required_variables` *(dict)* — Map of variable which must be present to error to display.
    Raises `errors.PluginError` — If one or more are missing.

def conf(var)
    Find a configuration value for variable `var`, as transformed by `mapper`.
    Parameters `var` *(str)* — The variable to get.
    Returns The value of the variable.
    Return type `str`
```

```python
certbot.plugins.dns_common.validate_file(filename)
Ensure that the specified file exists.
```

```python
certbot.plugins.dns_common.validate_file_permissions(filename)
Ensure that the specified file exists and warn about unsafe permissions.
```

```python
certbot.plugins.dns_common.base_domain_name_guesses(domain)
Return a list of progressively less-specific domain names.
One of these will probably be the domain name known to the DNS provider.
```

```
Example
>>> base_domain_name_guesses('foo.bar.baz.example.com')
['foo.bar.baz.example.com', 'bar.baz.example.com', 'baz.example.com', 'example.com →', 'com']
```

Parameters `domain` *(str)* — The domain for which to return guesses.

Returns The a list of less specific domain names.

Return type `list`
certbot.plugins.dns_common_lexicon module

Common code for DNS Authenticator Plugins built on Lexicon.

class certbot.plugins.dns_common_lexicon.LexiconClient
    Bases: object

    Encapsulates all communication with a DNS provider via Lexicon.

    add_txt_record(domain, record_name, record_content)
        Add a TXT record using the supplied information.
        Parameters
        • domain (str) – The domain to use to look up the managed zone.
        • record_name (str) – The record name (typically beginning with ‘_acme-challenge.’).
        • record_content (str) – The record content (typically the challenge validation).
        Raises errors.PluginError – if an error occurs communicating with the DNS Provider API

    del_txt_record(domain, record_name, record_content)
        Delete a TXT record using the supplied information.
        Parameters
        • domain (str) – The domain to use to look up the managed zone.
        • record_name (str) – The record name (typically beginning with ‘_acme-challenge.’).
        • record_content (str) – The record content (typically the challenge validation).
        Raises errors.PluginError – if an error occurs communicating with the DNS Provider API

    certbot.plugins.dns_common_lexicon.build_lexicon_config(lexicon_provider_name: str, lexicon_options: Dict, provider_options: Dict) -> Union[lexicon.config.ConfigResolver, Dict]

        Convenient function to build a Lexicon 2.x/3.x config object.
        :param str lexicon_provider_name: the name of the lexicon provider to use
        :param dict lexicon_options: options specific to lexicon
        :param dict provider_options: options specific to provider
        :return: configuration to apply to the provider
        :rtype: ConfigurationResolver or dict

certbot.plugins.dns_test_common module

Base test class for DNS authenticators.

class certbot.plugins.dns_test_common.BaseAuthenticatorTest
    Bases: object

    A base test class to reduce duplication between test code for DNS Authenticator Plugins.

    Assumes:
    • That subclasses also subclass unittest.TestCase
    • That the authenticator is stored as self.auth

    achall = KeyAuthorizationAnnotatedChallenge(challb=DNS01(token=b'17817c66b60ce2e4012df4b0609f2e9427f73b28'))
test_more_info()
test_get_chall_pref()
test_parser_arguments()
certbot.plugins.dns_test_common.write(values, path)
Write the specified values to a config file.

Parameters

• values (dict) – A map of values to write.
• path (str) – Where to write the values.

certbot.plugins.dns_test_common_lexicon module

Base test class for DNS authenticators built on Lexicon.

class certbot.plugins.dns_test_common_lexicon.BaseLexiconAuthenticatorTest
    Bases: certbot.plugins.dns_test_common.BaseAuthenticatorTest
test_perform()
test_cleanup()

class certbot.plugins.dns_test_common_lexicon.BaseLexiconClientTest
    Bases: object
    DOMAIN_NOT_FOUND = Exception('No domain found')
    GENERIC_ERROR
        alias of requests.exceptions.RequestException
    LOGIN_ERROR = HTTPError('400 Client Error: ...')
    UNKNOWN_LOGIN_ERROR = HTTPError('500 Surprise! Error: ...')
    record_prefix = '_acme-challenge'
    record_name = '_acme-challenge.example.com'
    record_content = 'bar'
test_add_txt_record()
test_add_txt_record_try_twice_to_find_domain()
test_add_txt_record_fail_to_find_domain()
test_add_txt_record_fail_to_authenticate()
test_add_txt_record_fail_to_authenticate_with_unknown_error()
test_add_txt_record_error_finding_domain()
test_add_txt_record_error_adding_record()
test_del_txt_record()
test_del_txt_record_fail_to_find_domain()
test_del_txt_record_fail_to_authenticate()
test_del_txt_record_fail_to_authenticate_with_unknown_error()
test_del_txt_record_error_finding_domain()
test_del_txt_record_error_deleting_record()

certbot.plugins.enhancements module

New interface style Certbot enhancements

certbot.plugins.enhancements.ENHANCEMENTS = ['redirect', 'ensure-http-header', 'ocsp-stapling']
List of possible certbot.interfaces.IInstaller enhancements.

List of expected options parameters:
- redirect: None
- ensure-http-header: name of header (i.e. Strict-Transport-Security)
- ocsp-stapling: certificate chain file path

certbot.plugins.enhancements.enabled_enhancements(config)
Generator to yield the enabled new style enhancements.

Parameters
config (certbot.interfaces.IConfig) – Configuration.

certbot.plugins.enhancements.are_requested(config)
Checks if one or more of the requested enhancements are those of the new enhancement interfaces.

Parameters
config (certbot.interfaces.IConfig) – Configuration.

certbot.plugins.enhancements.are_supported(config, installer)
Checks that all of the requested enhancements are supported by the installer.

Parameters
• config (certbot.interfaces.IConfig) – Configuration.
• installer (interfaces.IInstaller) – Installer object

Returns
If all the requested enhancements are supported by the installer

Return type
bool

certbot.plugins.enhancements.enable(lineage, domains, installer, config)
Run enable method for each requested enhancement that is supported.

Parameters
• lineage (certbot.interfaces.RenewableCert) – Certificate lineage object
• domains (str) – List of domains in certificate to enhance
• installer (interfaces.IInstaller) – Installer object
• config (certbot.interfaces.IConfig) – Configuration.

certbot.plugins.enhancements.populate_cli(add)
Populates the command line flags for certbot._internal.cli.HelpfulParser

Parameters
add (func) – Add function of certbot._internal.cli.HelpfulParser

class certbot.plugins.enhancements.AutoHSTSEnhancement
Bases: object

Enhancement interface that installer plugins can implement in order to provide functionality that configures the software to have a ‘Strict-Transport-Security’ with initially low max-age value that will increase over time.

The plugins implementing new style enhancements are responsible of handling the saving of configuration checkpoints as well as calling possible restarts of managed software themselves. For update_autohsts method, the installer may have to call prepare() to finalize the plugin initialization.
Methods: enable_autohsts is called when the header is initially installed using a low max-age value.

update_autohsts is called every time Certbot is run using ‘renew’ verb. The max-age value should be increased over time using this method.

deploy_autohsts is called for every lineage that has had its certificate renewed. A long HSTS max-age value should be set here, as we should be confident that the user is able to automatically renew their certificates.

abstract update_autohsts (lineage, *args, **kwargs)

Gets called for each lineage every time Certbot is run with ‘renew’ verb. Implementation of this method should increase the max-age value.

Parameters

- lineage (certbot.interfaces.RenewableCert) – Certificate lineage object

Note: prepare() method inherited from interfaces.IPlugin might need to be called manually within implementation of this interface method to finalize the plugin initialization.

abstract deploy_autohsts (lineage, *args, **kwargs)

Gets called for a lineage when its certificate is successfully renewed. Long max-age value should be set in implementation of this method.

Parameters

- lineage (certbot.interfaces.RenewableCert) – Certificate lineage object

abstract enable_autohsts (lineage, domains, *args, **kwargs)

Enables the AutoHSTS enhancement, installing Strict-Transport-Security header with a low initial value to be increased over the subsequent runs of Certbot renew.

Parameters

- lineage (certbot.interfaces.RenewableCert) – Certificate lineage object
- domains (list of str) – List of domains in certificate to enhance

certbot.plugins.storage module

Plugin storage class.

class certbot.plugins.storage.PluginStorage (config, classkey)

Bases: object

Class implementing storage functionality for plugins

save ()

Saves PluginStorage content to disk

Raises errors.PluginStorageError – when unable to serialize the data or write it to the filesystem

put (key, value)

Put configuration value to PluginStorage

Parameters

- key (str) – Key to store the value to
- value – Data to store
**fetch**(*key*)
Get configuration value from PluginStorage

Parameters **key** *(str)* – Key to get value from the storage

Raises **KeyError** – If the key doesn’t exist in the storage

### certbot.plugins.util module

Plugin utilities.

certbot.plugins.util.get_prefixes(*path*)
Retrieves all possible path prefixes of a path, in descending order of length. For instance:

- (Linux) /a/b/c returns [’/a/b/c’, ’/a/b’, ’/a’, ’/’]
- (Windows) C:abc returns [’C:abc’, ’C:ab’, ’C:a’, ’C:]’

Parameters **path** *(str)* – the path to break into prefixes

Returns all possible path prefixes of given path in descending order

Return type **list** of **str**

certbot.plugins.util.path_surgery(*cmd*)
Attempt to perform PATH surgery to find cmd

Mitigates https://github.com/certbot/certbot/issues/1833

Parameters **cmd** *(str)* – the command that is being searched for in the PATH

Returns True if the operation succeeded, False otherwise

### certbot.tests package

Utilities for running Certbot tests

### Submodules

### certbot.tests.acme_util module

ACME utilities for testing.

certbot.tests.acme_util.gen_combos(*challbs*)
Generate natural combinations for challbs.

certbot.tests.acme_util.chall_to_challb(*chall, status*)
Return ChallengeBody from Challenge.

certbot.tests.acme_util.gen_authzr(*authz_status, domain, challs, statuses, combos=True*)
Generate an authorization resource.

Parameters

- **authz_status** *(acme.messages.Status)* – Status object
- **challs** *(list)* – Challenge objects
- **statuses** *(list)* – status of each challenge object
• **combos** (*bool*) – Whether or not to add combinations

### certbot.tests.util module

Test utilities.

- **certbot.tests.util.vector_path** (*names*)
  Path to a test vector.

- **certbot.tests.util.load_vector** (*names*)
  Load contents of a test vector.

- **certbot.tests.util.load_cert** (*names*)
  Load certificate.

- **certbot.tests.util.load_csr** (*names*)
  Load certificate request.

- **certbot.tests.util.load_comparable_csr** (*names*)
  Load ComparableX509 certificate request.

- **certbot.tests.util.load_rsa_private_key** (*names*)
  Load RSA private key.

- **certbot.tests.util.load_pyopenssl_private_key** (*names*)
  Load pyOpenSSL private key.

- **certbot.tests.util.make_lineage** (config_dir, testfile, *ec=False*)
  Creates a lineage defined by testfile.
  This creates the archive, live, and renewal directories if necessary and creates a simple lineage.

  **Parameters**

  - **config_dir** (*str*) – path to the configuration directory
  - **testfile** (*str*) – configuration file to base the lineage on

  **Returns** path to the renewal conf file for the created lineage

  **Return type** *str*

- **certbot.tests.util.patch_get_utility** (target=`zope.component.getUtility`) Patch zope.component.getUtility to use a special mock IDisplay.

  The mock IDisplay works like a regular mock object, except it also also asserts that methods are called with valid arguments.

  **Parameters** **target** (*str*) – path to patch

  **Returns** mock zope.component.getUtility

  **Return type** mock.MagicMock

- **certbot.tests.util.patch_get_utility_with_stdout** (target=`zope.component.getUtility`, stdout=None) Patch zope.component.getUtility to use a special mock IDisplay.

  The mock IDisplay works like a regular mock object, except it also also asserts that methods are called with valid arguments.

  The *message* argument passed to the IDisplay methods is passed to stdout’s write method.

  **Parameters**
- **target** (*str*) – path to patch
- **stdout** (*object*) – object to write standard output to; it is expected to have a `write` method

**Returns** mock zope.component.getUtility

**Return type** mock.MagicMock

class certbot.tests.util.FreezableMock(frozen=False, func=None, return_value=sentinel.DEFAULT)

Bases: object

Mock object with the ability to freeze attributes.

This class works like a regular mock.MagicMock object, except attributes and behavior set before the object is frozen cannot be changed during tests.

If a `func` argument is provided to the constructor, this function is called first when an instance of FreezableMock is called, followed by the usual behavior defined by MagicMock. The return value of `func` is ignored.

freeze()

Freeze object preventing further changes.

class certbot.tests.util.TempDirTestCase(methodName='runTest')

Bases: unittest.case.TestCase

Base test class which sets up and tears down a temporary directory

setUp()

Execute before test

tearDown()

Execute after test

class certbot.tests.util.ConfigTestCase(methodName='runTest')

Bases: certbot.tests.util.TempDirTestCase

Test class which sets up a NamespaceConfig object.

setUp()

Execute before test

certbot.tests.util.lock_and_call(callback, path_to_lock)

Grab a lock on `path_to_lock` from a foreign process then execute the callback.  :param callable callback: object to call after acquiring the lock  :param str path_to_lock: path to file or directory to lock

certbot.tests.util.skip_on_windows(reason)

Decorator to skip permanently a test on Windows.  A reason is required.

certbot.tests.util.temp_join(path)

Return the given path joined to the tempdir path for the current platform  Eg.: ‘cert’ => /tmp/cert (Linux) or  ‘C:UserscurrentuserAppDataTempcert’ (Windows)

9.1. certbot package
9.1.2 Submodules

certbot.achallenges module

Client annotated ACME challenges.

Please use names such as `achall` to distinguish from variables “of type” `acme.challenges.Challenge` (denoted by `chall`) and `ChallengeBody` (denoted by `challb`):

```python
from acme import challenges
from acme import messages
from certbot import achallenges

chall = challenges.DNS(token='foo')
challb = messages.ChallengeBody(chall=chall)
achall = achallenges.DNS(chall=challb, domain='example.com')
```

Note, that all annotated challenges act as a proxy objects:

```python
achall.token == challb.token
```

class certbot.achallenges.AnnotatedChallenge(**kwargs)

Bases: josepy.util.ImmutableMap

Client annotated challenge.

Variables `challb` – Wrapped `ChallengeBody`.

chall

class certbot.achallenges.KeyAuthorizationAnnotatedChallenge(**kwargs)

Bases: certbot.achallenges.AnnotatedChallenge

Client annotated KeyAuthorizationChallenge challenge.

response_and_validation(*args, **kwargs)

Generate response and validation.

challb
domain
account_key

class certbot.achallenges.DNS(**kwargs)

Bases: certbot.achallenges.AnnotatedChallenge

Client annotated “dns” ACME challenge.

acme_type

alias of `acme.challenges.DNS`

challb
domain
**Certbot crypto_util module**

Certbot client crypto utility functions.

```
certbot.crypto_util.init_save_key(key_size, key_dir, key_type='rsa', elliptic_curve='secp256r1', keyname='key-certbot.pem')
```

Initializes and saves a privkey.

```
inits key and saves it in PEM format on the filesystem.
```

**Note:** keyname is the attempted filename, it may be different if a file already exists at the path.

**Parameters**

- `key_size (int)` – key size in bits if key size is rsa.
- `key_dir (str)` – Key save directory.
- `key_type (str)` – Key Type [rsa, ecdsa]
- `elliptic_curve (str)` – Name of the elliptic curve if key type is ecdsa.
- `keyname (str)` – Filename of key

**Returns** Key

**Return type** `certbot.util.Key`

**Raises** `ValueError` – If unable to generate the key given key_size.

```
certbot.crypto_util.init_save_csr(privkey, names, path)
```

Initialize a CSR with the given private key.

**Parameters**

- `privkey (certbot.util.Key)` – Key to include in the CSR
- `names (set)` – str names to include in the CSR
- `path (str)` – Certificate save directory.

**Returns** CSR

**Return type** `certbot.util.CSR`

```
certbot.crypto_util.valid_csr(csr)
```

Validate CSR.

Check if csr is a valid CSR for the given domains.

**Parameters** `csr (str)` – CSR in PEM.

**Returns** Validity of CSR.

**Return type** bool

```
certbot.crypto_util.csr_matches_pubkey(csr, privkey)
```

Does private key correspond to the subject public key in the CSR?

**Parameters**

- `csr (str)` – CSR in PEM.
- `privkey (str)` – Private key file contents (PEM)

**Returns** Correspondence of private key to CSR subject public key.
Return type bool
certbot.crypto_util.import_csr_file(csrfile, data)
Import a CSR file, which can be either PEM or DER.

Parameters
• csrfile (str) – CSR filename
• data (str) – contents of the CSR file

Returns (crypto.FILETYPE_PEM, util.CSR object representing the CSR, list of domains requested in the CSR)
Return type tuple
certbot.crypto_util.make_key(bits=1024, key_type='rsa', elliptic_curve=None)
Generate PEM encoded RSA|EC key.

Parameters
• bits (int) – Number of bits if key_type=rsa. At least 1024 for RSA.
• ec_curve (str) – The elliptic curve to use.

Returns new RSA or ECDSA key in PEM form with specified number of bits or of type ec_curve when key_type ecdsa is used.
Return type str
certbot.crypto_util.valid_privkey(privkey)
Is valid RSA private key?

Parameters privkey (str) – Private key file contents in PEM

Returns Validity of private key.
Return type bool
certbot.crypto_util.verify_renewable_cert(renewable_cert)
For checking that your certs were not corrupted on disk.

Several things are checked:
1. Signature verification for the cert.
2. That fullchain matches cert and chain when concatenated.
3. Check that the private key matches the certificate.

Parameters renewable_cert(certbot.interfaces.RenewableCert) – cert to verify

Raises errors.Error – If verification fails.
certbot.crypto_util.verify_renewable_cert_sig(renewable_cert)
Verifies the signature of a RenewableCert object.

Parameters renewable_cert(certbot.interfaces.RenewableCert) – cert to verify

Raises errors.Error – If signature verification fails.
certbot.crypto_util.verify_signed_payload(public_key, signature, payload, signature_hash_algorithm)
Check the signature of a payload.

Parameters
• **public_key** (`RSAPublicKey/EllipticCurvePublicKey`) – the public_key to check signature
• **signature** (`bytes`) – the signature bytes
• **payload** (`bytes`) – the payload bytes
• **signature_hash_algorithm** (`cryptography.hazmat.primitives.hashes.HashAlgorithm`) – algorithm used to hash the payload

**Raises**

• **InvalidSignature** – If signature verification fails.
• **errors.Error** – If public key type is not supported

`certbot.crypto_util.verify_cert_matches_priv_key(cert_path, key_path)`
Verifies that the private key and cert match.

**Parameters**

• **cert_path** (`str`) – path to a cert in PEM format
• **key_path** (`str`) – path to a private key file

**Raises** **errors.Error** – If they don’t match.

`certbot.crypto_util.verify_fullchain(renewable_cert)`
Verifies that fullchain is indeed cert concatenated with chain.

**Parameters** **renewable_cert** (`certbot.interfaces.RenewableCert`) – cert to verify

**Raises** **errors.Error** – If cert and chain do not combine to fullchain.

`certbot.crypto_util.pyopenssl_load_certificate(data)`
Load PEM/DER certificate.

**Raises** **errors.Error** –

`certbot.crypto_util.get_sans_from_cert(cert, typ=1)`
Get a list of Subject Alternative Names from a certificate.

**Parameters**

• **cert** (`str`) – Certificate (encoded).

• **typ** – crypto.FILETYPE_PEM or crypto.FILETYPE_ASN1

**Returns** A list of Subject Alternative Names.

**Return type** `list`

`certbot.crypto_util.get_names_from_cert(csr, typ=1)`
Get a list of domains from a cert, including the CN if it is set.

**Parameters**

• **cert** (`str`) – Certificate (encoded).

• **typ** – crypto.FILETYPE_PEM or crypto.FILETYPE_ASN1

**Returns** A list of domain names.

**Return type** `list`

`certbot.crypto_util.dump_pyopenssl_chain(chain, filetype=1)`
Dump certificate chain into a bundle.
Parameters `chain` *(list)* – List of crypto.X509 (or wrapped in josepy.util.
ComparableX509).

`certbot.crypto_util.notBefore(cert_path)`
When does the cert at cert_path start being valid?

Parameters `cert_path` *(str)* – path to a cert in PEM format.

Returns the notBefore value from the cert at cert_path.

Return type `datetime.datetime`

`certbot.crypto_util.notAfter(cert_path)`
When does the cert at cert_path stop being valid?

Parameters `cert_path` *(str)* – path to a cert in PEM format.

Returns the notAfter value from the cert at cert_path.

Return type `datetime.datetime`

`certbot.crypto_util.sha256sum(filename)`
Compute a sha256sum of a file.

NB: In given file, platform specific newlines characters will be converted into their equivalent unicode counterparts before calculating the hash.

Parameters `filename` *(str)* – path to the file whose hash will be computed.

Returns sha256 digest of the file in hexadecimal.

Return type `str`

`certbot.crypto_util.cert_and_chain_from_fullchain(fullchain_pem)`
Split fullchain_pem into cert_pem and chain_pem.

Parameters `fullchain_pem` *(str)* – concatenated cert + chain.

Returns tuple of string cert_pem and chain_pem.

Return type `tuple`

Raises `errors.Error` – If there are less than 2 certificates in the chain.

`certbot.crypto_util.get_serial_from_cert(cert_path)`
Retrieve the serial number of a certificate from certificate path.

Parameters `cert_path` *(str)* – path to a cert in PEM format.

Returns serial number of the certificate.

Return type `int`

`certbot.crypto_util.find_chain_with_issuer(fullchains, issuer_cn, warn_on_no_match=False)`
Chooses the first certificate chain from fullchains whose topmost intermediate has an Issuer Common Name matching issuer_cn (in other words the first chain which chains to a root whose name matches issuer_cn).

Parameters

- `fullchains` *(list of str)* – The list of fullchains in PEM chain format.
- `issuer_cn` *(str)* – The exact Subject Common Name to match against any issuer in the certificate chain.

Returns The best-matching fullchain, PEM-encoded, or the first if none match.

Return type `str`
certbot.errors module

Certbot client errors.

**exception** certbot.errors.Error
   Bases: Exception
   Generic Certbot client error.

**exception** certbot.errors.AccountStorageError
   Bases: certbot.errors.Error
   Generic AccountStorage error.

**exception** certbot.errors.AccountNotFound
   Bases: certbot.errors.AccountStorageError
   Account not found error.

**exception** certbot.errors.ReverterError
   Bases: certbot.errors.Error
   Certbot Reverter error.

**exception** certbot.errors.SubprocessError
   Bases: certbot.errors.Error
   Subprocess handling error.

**exception** certbot.errors.CertStorageError
   Bases: certbot.errors.Error
   Generic CertStorage error.

**exception** certbot.errors.HookCommandNotFound
   Bases: certbot.errors.Error
   Failed to find a hook command in the PATH.

**exception** certbot.errors.SignalExit
   Bases: certbot.errors.Error
   A Unix signal was received while in the ErrorHandler context manager.

**exception** certbot.errors.OverlappingMatchFound
   Bases: certbot.errors.Error
   Multiple lineages matched what should have been a unique result.

**exception** certbot.errors.LockError
   Bases: certbot.errors.Error
   File locking error.

**exception** certbot.errors.AuthorizationError
   Bases: certbot.errors.Error
   Authorization error.

**exception** certbot.errors.FailedChallenges (failed_achalls)
   Bases: certbot.errors.AuthorizationError
   Failed challenges error.

   Variables **failed_achalls** (set) – Failed AnnotatedChallenge instances.
exception certbot.errors.PluginError
    Bases: certbot.errors.Error
    Certbot Plugin error.

exception certbot.errors.PluginEnhancementAlreadyPresent
    Bases: certbot.errors.Error
    Enhancement was already set

exception certbot.errors.PluginSelectionError
    Bases: certbot.errors.Error
    A problem with plugin/configurator selection or setup

exception certbot.errors.NoInstallationError
    Bases: certbot.errors.PluginError
    Certbot No Installation error.

exception certbot.errors.MisconfigurationError
    Bases: certbot.errors.PluginError
    Certbot Misconfiguration error.

exception certbot.errors.NotSupportedError
    Bases: certbot.errors.PluginError
    Certbot Plugin function not supported error.

exception certbot.errors.PluginStorageError
    Bases: certbot.errors.PluginError
    Certbot Plugin Storage error.

exception certbot.errors.StandaloneBindError (socket_error, port)
    Bases: certbot.errors.Error
    Standalone plugin bind error.

exception certbot.errors.ConfigurationError
    Bases: certbot.errors.Error
    Configuration sanity error.

exception certbot.errors.MissingCommandlineFlag
    Bases: certbot.errors.Error
    A command line argument was missing in noninteractive usage

certbot.interfaces module

Certbot client interfaces.

class certbot.interfaces.AccountStorage
    Bases: object
    Accounts storage interface.

    abstract find_all()
    Find all accounts.

    Returns All found accounts.

    Return type list
abstract load (account_id)
Load an account by its id.

Raises
• AccountNotFound – if account could not be found
• AccountStorageError – if account could not be loaded

abstract save (account, client)
Save account.

Raises AccountStorageError – if account could not be saved

interface certbot.interfaces.IPluginFactory
IPlugin factory.

Objects providing this interface will be called without satisfying any entry point “extras” (extra dependencies) you might have defined for your plugin, e.g (excerpt from setup.py script):

```python
setup(
    ...
    entry_points={
        'certbot.plugins': [
            'name=example_project.plugin[plugin_deps]',
        ],
    },
    extras_require={
        'plugin_deps': ['dep1', 'dep2'],
    }
)
```

Therefore, make sure such objects are importable and usable without extras. This is necessary, because CLI does the following operations (in order):

• loads an entry point,
• calls inject_parser_options,
• requires an entry point,
• creates plugin instance (__call__).

description
Short plugin description

__call__ (config, name)
Create new IPlugin.

Parameters
• config (IConfig) – Configuration.
• name (str) – Unique plugin name.

inject_parser_options (parser, name)
Inject argument parser options (flags).

1. Be nice and prepend all options and destinations with option_namespace and dest_namespace.
2. Inject options (flags) only. Positional arguments are not allowed, as this would break the CLI.

Parameters
• parser (ArgumentParser) – (Almost) top-level CLI parser.
• **name** *(str)* – Unique plugin name.

```python
interface certbot.interfaces.IPlugin
Cerbot plugin.
```

```python
prepare()
Prepare the plugin.
Finish up any additional initialization.
```

**Raises**

• **PluginError** – when full initialization cannot be completed.

• **MisconfigurationError** – when full initialization cannot be completed. Plugin will be displayed on a list of available plugins.

• **NoInstallationError** – when the necessary programs/files cannot be located. Plugin will NOT be displayed on a list of available plugins.

• **NotSupportedError** – when the installation is recognized, but the version is not currently supported.

```python
more_info()
```

Human-readable string to help the user.

Should describe the steps taken and any relevant info to help the user decide which plugin to use.

**Rtype** str

```python
interface certbot.interfaces.IAuthenticator
Extends: certbot.interfaces.IPlugin
```

Generic Cerbot Authenticator.

Class represents all possible tools processes that have the ability to perform challenges and attain a certificate.

```python
def get_chall_pref(domain)
Return collections.Iterable of challenge preferences.
```

**Parameters** domain *(str)* – Domain for which challenge preferences are sought.

**Returns** collections.Iterable of challenge types (subclasses of acme.challenges.Challenge) with the most preferred challenges first. If a type is not specified, it means the Authenticator cannot perform the challenge.

**Return type** collections.Iterable

```python
perform(achalls)
Perform the given challenge.
```

**Parameters** achalls *(list)* – Non-empty (guaranteed) list of AnnotatedChallenge instances, such that it contains types found within get_chall_pref() only.

**Returns** collections.Iterable of ACME ChallengeResponse instances corresponding to each provided Challenge.

**Return type** collections.Iterable of acme.challenges.ChallengeResponse, where responses are required to be returned in the same order as corresponding input challenges

**Raises** PluginError – If some or all challenges cannot be performed

```python
cleanup(achalls)
Revert changes and shutdown after challenges complete.
```
This method should be able to revert all changes made by perform, even if perform exited abnormally.

**Parameters**

- `achalls` *(list)* – Non-empty (guaranteed) list of `AnnotatedChallenge` instances, a subset of those previously passed to `perform()`.

**Raises** `PluginError` – if original configuration cannot be restored

**interface** `certbot.interfaces.IConfig`

Certbot user-supplied configuration.

---

**Warning**: The values stored in the configuration have not been filtered, stripped or sanitized.

- `server`  
  ACME Directory Resource URI.

- `email`  
  Email used for registration and recovery contact. Use comma to register multiple emails, ex: `u1@example.com,u2@example.com`. (default: Ask).

- `rsa_key_size`  
  Size of the RSA key.

- `elliptic_curve`  
  The SECG elliptic curve name to use. Please see RFC 8446 for supported values.

- `key_type`  
  Type of generated private key (Only ONE per invocation can be provided at this time)

- `must_staple`  
  Adds the OCSP Must Staple extension to the certificate. Autoconfigures OCSP Stapling for supported setups (Apache version >= 2.3.3).

- `config_dir`  
  Configuration directory.

- `work_dir`  
  Working directory.

- `accounts_dir`  
  Directory where all account information is stored.

- `backup_dir`  
  Configuration backups directory.

- `csr_dir`  
  Directory where newly generated Certificate Signing Requests (CSRs) are saved.

- `in_progress_dir`  
  Directory used before a permanent checkpoint is finalized.

- `key_dir`  
  Keys storage.

- `temp_checkpoint_dir`  
  Temporary checkpoint directory.

- `no_verify_ssl`  
  Disable verification of the ACME server’s certificate.

- `http01_port`  
  Port used in the http-01 challenge. This only affects the port Certbot listens on. A conforming ACME server will still attempt to connect on port 80.
**http01_address**
The address the server listens to during http-01 challenge.

**https_port**
Port used to serve HTTPS. This affects which port Nginx will listen on after a LE certificate is installed.

**pref_challs**
Sorted user specified preferred challenge type strings with the most preferred challenge listed first.

**allow_subset_of_names**
When performing domain validation, do not consider it a failure if authorizations can not be obtained for a strict subset of the requested domains. This may be useful for allowing renewals for multiple domains to succeed even if some domains no longer point at this system. This is a boolean.

**strict_permissions**
Require that all configuration files are owned by the current user; only needed if your config is somewhere unsafe like /tmp/. This is a boolean.

**disable_renew_updates**
If updates provided by installer enhancements when Certbot is being run with “renew” verb should be disabled.

**preferred_chain**
If the CA offers multiple certificate chains, prefer the chain whose topmost certificate was issued from this Subject Common Name. If no match, the default offered chain will be used.

---

### interface certbot.interfaces.IInstaller

**Extends:** `certbot.interfaces.IPlugin`

Generic Certbot Installer Interface.

Represents any server that an X509 certificate can be placed.

It is assumed that `save()` is the only method that finalizes a checkpoint. This is important to ensure that checkpoints are restored in a consistent manner if requested by the user or in case of an error.

Using `certbot.reverter.Reverter` to implement checkpoints, rollback, and recovery can dramatically simplify plugin development.

**get_all_names()**
Returns all names that may be authenticated.

**Return type** `collections.Iterable of str`

**deploy_cert(domain, cert_path, key_path, chain_path, fullchain_path)**
Deploy certificate.

**Parameters**
- `domain (str)` – domain to deploy certificate file
- `cert_path (str)` – absolute path to the certificate file
- `key_path (str)` – absolute path to the private key file
- `chain_path (str)` – absolute path to the certificate chain file
- `fullchain_path (str)` – absolute path to the certificate fullchain file (cert plus chain)

**Raises** `PluginError` – when cert cannot be deployed

**enhance(domain, enhancement, options=None)**
Perform a configuration enhancement.

**Parameters**
• **domain** *(str)* – domain for which to provide enhancement

• **enhancement** *(str)* – An enhancement as defined in `ENHANCEMENTS`

• **options** – Flexible options parameter for enhancement. Check documentation of `ENHANCEMENTS` for expected options for each enhancement.

Raises **PluginError** – If Enhancement is not supported, or if an error occurs during the enhancement.

**supported_enhancements ()**

Returns a `collections.Iterable` of supported enhancements.

**Returns** supported enhancements which should be a subset of `ENHANCEMENTS`

**Return type** `collections.Iterable` of `str`

**save** *(title=None, temporary=False)*

Saves all changes to the configuration files.

Both title and temporary are needed because a save may be intended to be permanent, but the save is not ready to be a full checkpoint.

It is assumed that at most one checkpoint is finalized by this method. Additionally, if an exception is raised, it is assumed a new checkpoint was not finalized.

**Parameters**

• **title** *(str)* – The title of the save. If a title is given, the configuration will be saved as a new checkpoint and put in a timestamped directory. `title` has no effect if `temporary` is true.

• **temporary** *(bool)* – Indicates whether the changes made will be quickly reversed in the future (challenges)

Raises **PluginError** – when save is unsuccessful

**rollback_checkpoints** *(rollback=1)*

Revert `rollback` number of configuration checkpoints.

**Raises** **PluginError** – when configuration cannot be fully reverted

**recovery_routine ()**

Revert configuration to most recent finalized checkpoint.

Remove all changes (temporary and permanent) that have not been finalized. This is useful to protect against crashes and other execution interruptions.

**Raises** **errors.PluginError** – If unable to recover the configuration

**config_test ()**

Make sure the configuration is valid.

**Raises** **MisconfigurationError** – when the config is not in a usable state

**restart ()**

Restart or refresh the server content.

** Raises** **PluginError** – when server cannot be restarted

**interface** `certbot.interfaces.IDisplay`

Generic display.

**notification** *(message, pause, wrap=True, force_interactive=False)*

Displays a string message
Parameters

- **message** (*str*) – Message to display
- **pause** (*bool*) – Whether or not the application should pause for confirmation (if available)
- **wrap** (*bool*) – Whether or not the application should wrap text
- **force_interactive** (*bool*) – True if it’s safe to prompt the user because it won’t cause any workflow regressions

`menu(message, choices, ok_label=None, cancel_label=None, help_label=None, default=None, cli_flag=None, force_interactive=False)`

Displays a generic menu.

When not setting `force_interactive=True`, you must provide a default value.

Parameters

- **message** (*str*) – message to display
- **choices** (*list of tuple() or str*) – choices
- **ok_label** (*str*) – label for OK button (UNUSED)
- **cancel_label** (*str*) – label for Cancel button (UNUSED)
- **help_label** (*str*) – label for Help button (UNUSED)
- **default** (*int*) – default (non-interactive) choice from the menu
- **cli_flag** (*str*) – to automate choice from the menu, eg “--keep”
- **force_interactive** (*bool*) – True if it’s safe to prompt the user because it won’t cause any workflow regressions

Returns tuple of (`code`, `index`) where `code` - str display exit code `index` - int index of the user’s selection

Raises `errors.MissingCommandlineFlag` – if called in non-interactive mode without a default set

`input(message, default=None, cli_args=None, force_interactive=False)`

Accept input from the user.

When not setting `force_interactive=True`, you must provide a default value.

Parameters

- **message** (*str*) – message to display to the user
- **default** (*str*) – default (non-interactive) response to prompt
- **force_interactive** (*bool*) – True if it’s safe to prompt the user because it won’t cause any workflow regressions

Returns tuple of (`code`, `input`) where `code` - str display exit code `input` - str of the user’s input

Return type tuple

Raises `errors.MissingCommandlineFlag` – if called in non-interactive mode without a default set

`yesno(message, yes_label='Yes', no_label='No', default=None, cli_args=None, force_interactive=False)`

Query the user with a yes/no question.
Yes and No label must begin with different letters.

When not setting force_interactive=True, you must provide a default value.

**Parameters**

- `message (str)` – question for the user
- `default (str)` – default (non-interactive) choice from the menu
- `cli_flag (str)` – to automate choice from the menu, eg “-redirect / –no-redirect”
- `force_interactive (bool)` – True if it’s safe to prompt the user because it won’t cause any workflow regressions

**Returns** True for “Yes”, False for “No”

**Return type** bool

**Raises** errors.MissingCommandlineFlag – if called in non-interactive mode without a default set

**checklist (message, tags, default=None, cli_args=None, force_interactive=False)**

Allow for multiple selections from a menu.

When not setting force_interactive=True, you must provide a default value.

**Parameters**

- `message (str)` – message to display to the user
- `tags (list)` – where each is of type str len(tags) > 0
- `default (str)` – default (non-interactive) state of the checklist
- `cli_flag (str)` – to automate choice from the menu, eg “-domains”
- `force_interactive (bool)` – True if it’s safe to prompt the user because it won’t cause any workflow regressions

**Returns** tuple of the form (code, list_tags) where code - int display exit code list_tags - list of str tags selected by the user

**Return type** tuple

**Raises** errors.MissingCommandlineFlag – if called in non-interactive mode without a default set

**directory_select (self, message, default=None, cli_flag=None, force_interactive=False)**

Display a directory selection screen.

When not setting force_interactive=True, you must provide a default value.

**Parameters**

- `message (str)` – prompt to give the user
- `default` – the default value to return, if one exists, when using the NoninteractiveDisplay
- `cli_flag (str)` – option used to set this value with the CLI, if one exists, to be included in error messages given by NoninteractiveDisplay
- `force_interactive (bool)` – True if it’s safe to prompt the user because it won’t cause any workflow regressions

**Returns** tuple of the form (code, string) where code - int display exit code string - input entered by the user
interface certbot.interfaces.IReporter
    Interface to collect and display information to the user.

    **HIGH_PRIORITY**
    Used to denote high priority messages

    **MEDIUM_PRIORITY**
    Used to denote medium priority messages

    **LOW_PRIORITY**
    Used to denote low priority messages

    `add_message(self, msg, priority, on_crash=True)`
    Adds `msg` to the list of messages to be printed.

    **Parameters**
    - `msg (str)` – Message to be displayed to the user.
    - `priority (int)` – One of **HIGH_PRIORITY**, **MEDIUM_PRIORITY**, or **LOW_PRIORITY**.
    - `on_crash (bool)` – Whether or not the message should be printed if the program exits abnormally.

    `print_messages(self)`
    Prints messages to the user and clears the message queue.

class certbot.interfaces.RenewableCert
    Bases: object

    Interface to a certificate lineage.

    **abstract property cert_path**
    Path to the certificate file.

    **Return type** str

    **abstract property key_path**
    Path to the private key file.

    **Return type** str

    **abstract property chain_path**
    Path to the certificate chain file.

    **Return type** str

    **abstract property fullchain_path**
    Path to the full chair file.

    The full chain is the certificate file plus the chain file.

    **Return type** str

    **abstract property lineagename**
    Name given to the certificate lineage.

    **Return type** str

    **abstract names()**
    What are the subject names of this certificate?

    **Returns** the subject names

    **Return type** list of str
Raises `CertStorageError` – if could not find cert file.

class certbot.interfaces.GenericUpdater
Bases: object

Interface for update types not currently specified by Certbot.

This class allows plugins to perform types of updates that Certbot hasn’t defined (yet).

To make use of this interface, the installer should implement the interface methods, and `interfaces.GenericUpdater.register(InstallerClass)` should be called from the installer code.

The plugins implementing this enhancement are responsible of handling the saving of configuration checkpoints as well as other calls to interface methods of `interfaces.IInstaller` such as `prepare()` and `restart()`

abstract generic_updates (lineage, *args, **kwargs)

Perform any update types defined by the installer.

If an installer is a subclass of the class containing this method, this function will always be called when “certbot renew” is run. If the update defined by the installer should be run conditionally, the installer needs to handle checking the conditions itself.

This method is called once for each lineage.

Parameters

- **lineage** (*RenewableCert*) – Certificate lineage object

class certbot.interfaces.RenewDeployer
Bases: object

Interface for update types run when a lineage is renewed

This class allows plugins to perform types of updates that need to run at lineage renewal that Certbot hasn’t defined (yet).

To make use of this interface, the installer should implement the interface methods, and `interfaces.RenewDeployer.register(InstallerClass)` should be called from the installer code.

abstract renew_deploy (lineage, *args, **kwargs)

Perform updates defined by installer when a certificate has been renewed

If an installer is a subclass of the class containing this method, this function will always be called when a certificate has been renewed by running “certbot renew”. For example if a plugin needs to copy a certificate over, or change configuration based on the new certificate.

This method is called once for each lineage renewed

Parameters

- **lineage** (*RenewableCert*) – Certificate lineage object

**certbot.main module**

Certbot main public entry point.

certbot.main.main (*cli_args=*$None*)

Run Certbot.

Parameters

- **cli_args** (*list of str*) – command line to Certbot, defaults to `sys.argv[1:]`

Returns

- value for `sys.exit` about the exit status of Certbot

Return type

- `str` or `int` or `None`
certbot.ocsp package

Tools for checking certificate revocation.

```python
class certbot.ocsp.RevocationChecker (enforce_openssl_binary_usage=False)
```

This class figures out OCSP checking on this system, and performs it.

```python
ocsp_revoked (cert: certbot.interfaces.RenewableCert) → bool
```

Get revoked status for a particular cert version.

- **Parameters**
  - `cert` (interfaces.RenewableCert) – Certificate object

- **Returns**
  - True if revoked; False if valid or the check failed or cert is expired.

- **Return type**
  - bool

```python
ocsp_revoked_by_paths (cert_path: str, chain_path: str, timeout: int = 10) → bool
```

Performs the OCSP revocation check

- **Parameters**
  - `cert_path` (str) – Certificate filepath
  - `chain_path` (str) – Certificate chain
  - `timeout` (int) – Timeout (in seconds) for the OCSP query

- **Returns**
  - True if revoked; False if valid or the check failed or cert is expired.

- **Return type**
  - bool

certbot.reverter module

Reverter class saves configuration checkpoints and allows for recovery.

```python
class certbot.reverter.Reverter (config)
```

Reverter Class - save and revert configuration checkpoints.

This class can be used by the plugins, especially Installers, to undo changes made to the user’s system. Modifications to files and commands to do undo actions taken by the plugin should be registered with this class before the action is taken.

Once a change has been registered with this class, there are three states the change can be in. First, the change can be a temporary change. This should be used for changes that will soon be reverted, such as config changes for the purpose of solving a challenge. Changes are added to this state through calls to `add_to_temp_checkpoint()` and reverted when `revert_temporary_config()` or `recovery_routine()` is called.

The second state a change can be in is in progress. These changes are not temporary, however, they also have not been finalized in a checkpoint. A change must become in progress before it can be finalized. Changes are added to this state through calls to `add_to_checkpoint()` and reverted when `recovery_routine()` is called.

The last state a change can be in is finalized in a checkpoint. A change is put into this state by first becoming an in progress change and then calling `finalize_checkpoint()`. Changes in this state can be reverted through calls to `rollback_checkpoints()`.
As a final note, creating new files and registering undo commands are handled specially and use the methods
\texttt{register\_file\_creation()} and \texttt{register\_undo\_command()} respectively. Both of these methods
can be used to create either temporary or in progress changes.

\textbf{Note:} Consider moving everything over to CSV format.

\textbf{Parameters} \texttt{config(certbot.interfaces.IConfig)} – Configuration.

\textbf{revert\_temporary\_config()} 
Reload users original configuration files after a temporary save.

This function should reinstall the users original configuration files for all saves with temporary=True

\textbf{Raises} \texttt{ReverterError} – when unable to revert config

\textbf{rollback\_checkpoints}(\texttt{rollback=1}) 
Revert ‘rollback’ number of configuration checkpoints.

\textbf{Parameters} \texttt{rollback(int)} – Number of checkpoints to reverse. A str num will be cast to
an integer. So “2” is also acceptable.

\textbf{Raises} \texttt{ReverterError} – if there is a problem with the input or if the function is unable to
correctly revert the configuration checkpoints

\textbf{add\_to\_temp\_checkpoint}(\texttt{save\_files, save\_notes}) 
Add files to temporary checkpoint.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{save\_files(set)} – set of filepaths to save
  \item \texttt{save\_notes(str)} – notes about changes during the save
\end{itemize}

\textbf{add\_to\_checkpoint}(\texttt{save\_files, save\_notes}) 
Add files to a permanent checkpoint.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{save\_files(set)} – set of filepaths to save
  \item \texttt{save\_notes(str)} – notes about changes during the save
\end{itemize}

\textbf{register\_file\_creation}(\texttt{temporary, *files}) 
Register the creation of all files during certbot execution.

Call this method before writing to the file to make sure that the file will be cleaned up if the program exits
unexpectedly. (Before a save occurs)

\textbf{Parameters}

\begin{itemize}
  \item \texttt{temporary(bool)} – If the file creation registry is for a temp or permanent save.
  \item \texttt{*files} – file paths (str) to be registered
\end{itemize}

\textbf{Raises} \texttt{certbot.errors.ReverterError} – If call does not contain necessary parameters
or if the file creation is unable to be registered.

\textbf{register\_undo\_command}(\texttt{temporary, command}) 
Register a command to be run to undo actions taken.
Warning: This function does not enforce order of operations in terms of file modification vs. command registration. All undo commands are run first before all normal files are reverted to their previous state. If you need to maintain strict order, you may create checkpoints before and after the command registration. This function may be improved in the future based on demand.

Parameters

- **temporary (bool)** – Whether the command should be saved in the IN_PROGRESS or TEMPORARY checkpoints.
- **command (list of str)** – Command to be run.

recovery_routine()
Revert configuration to most recent finalized checkpoint.
Remove all changes (temporary and permanent) that have not been finalized. This is useful to protect against crashes and other execution interruptions.

Raises **errors.ReverterError** – If unable to recover the configuration

finalize_checkpoint (**title**)
Finalize the checkpoint.
Timestamps and permanently saves all changes made through the use of add_to_checkpoint() and register_file_creation()

Parameters **title (str)** – Title describing checkpoint

Raises **certbot.errors.ReverterError** – when the checkpoint is not able to be finalized.

certbot.util module
Utilities for all Certbot.

class certbot.util.Key (**file, pem**)
Bases: tuple

    file
    Alias for field number 0

    pem
    Alias for field number 1

class certbot.util.CSR (**file, data, form**)
Bases: tuple

    data
    Alias for field number 1

    file
    Alias for field number 0

    form
    Alias for field number 2

certbot.util.env_no_snap_for_external_calls()
When Certbot is run inside a Snap, certain environment variables are modified. But Certbot sometimes calls out to external programs, since it uses classic confinement. When we do that, we must modify the env to remove our modifications so it will use the system’s libraries, since they may be incompatible with the versions of libraries.
included in the Snap. For example, apachectl, Nginx, and anything run from inside a hook should call this function and pass the results into the `env` argument of `subprocess.Popen`.

**Returns** A modified copy of `os.environ` ready to pass to `Popen`

**Return type** `dict`

certbot.util.run_script(params, log=<bound method Logger.error of <Logger certbot.util (WARNING)>>)

Run the script with the given params.

**Parameters**

- `params (list)` – List of parameters to pass to Popen
- `log (callable)` – Logger method to use for errors

certbot.util.exe_exists(exe)

Determine whether path/name refers to an executable.

**Parameters**

- `exe (str)` – Executable path or name

**Returns** If exe is a valid executable

**Return type** `bool`

certbot.util.lock_dir_until_exit(dir_path)

Lock the directory at `dir_path` until program exit.

**Parameters**

- `dir_path (str)` – path to directory

**Raises** `errors.LockError` – if the lock is held by another process

certbot.util.set_up_core_dir(directory, mode, strict)

Ensure directory exists with proper permissions and is locked.

**Parameters**

- `directory (str)` – Path to a directory.
- `mode (int)` – Directory mode.
- `strict (bool)` – require directory to be owned by current user

**Raises**

- `errors.LockError` – if the directory cannot be locked
- `errors.Error` – if the directory cannot be made or verified

certbot.util.make_or_verify_dir(directory, mode=493, strict=False)

Make sure directory exists with proper permissions.

**Parameters**

- `directory (str)` – Path to a directory.
- `mode (int)` – Directory mode.
- `strict (bool)` – require directory to be owned by current user

**Raises**

- `errors.Error` – if a directory already exists, but has wrong permissions or owner
- `OSError` – if invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.
certbot.util.safe_open(path, mode='w', chmod=None)
Safely open a file.

Parameters
• path (str) – Path to a file.
• mode (str) – Same os mode for open.
• chmod (int) – Same as mode for filesystem.open, uses Python defaults if None.

certbot.util.unique_file(path, chmod=511, mode='w')
Safely finds a unique file.

Parameters
• path (str) – path/filename.ext
• chmod (int) – File mode
• mode (str) – Open mode

Returns tuple of file object and file name

certbot.util.unique_lineage_name(path, filename, chmod=420, mode='w')
Safely finds a unique file using lineage convention.

Parameters
• path (str) – directory path
• filename (str) – proposed filename
• chmod (int) – file mode
• mode (str) – open mode

Returns tuple of file object and file name (which may be modified from the requested one by appending digits to ensure uniqueness)

Raises OSError – if writing files fails for an unanticipated reason, such as a full disk or a lack of permission to write to specified location.

certbot.util.safely_remove(path)
Remove a file that may not exist.

certbot.util.get_filtered_names(all_names)
Removes names that aren’t considered valid by Let’s Encrypt.

Parameters all_names (set) – all names found in the configuration

Returns all found names that are considered valid by LE

Return type set

certbot.util.get_os_info()
Get OS name and version

Returns (os_name, os_version)

Return type tuple of str

certbot.util.get_os_info_ua()
Get OS name and version string for User Agent

Returns os_ua

Return type str
certbot.util.get_systemd_os_like()  
Get a list of strings that indicate the distribution likeness to other distributions.

    Returns: List of distribution acronyms  
    Return type: list of str

certbot.util.get_var_from_file(varname, filepath='/etc/os-release')  
Get single value from a file formatted like systemd /etc/os-release

    Parameters:  
        • varname (str) – Name of variable to fetch  
        • filepath (str) – File path of os-release file

    Returns: requested value  
    Return type: str

certbot.util.get_python_os_info(pretty=False)  
Get Operating System type/distribution and major version using python platform module

    Parameters:  
        pretty (bool) – If the returned OS name should be in longer (pretty) form

    Returns: (os_name, os_version)  
    Return type: tuple of str

certbot.util.safe_email(email)  
Scrub email address before using it.

certbot.util.DeprecatedArgumentAction(option_strings, dest, nargs=None, const=None, default=None, type=None, choices=None, required=False, help=None, metavar=None)  
Bases: argparse.Action

Action to log a warning when an argument is used.

certbot.util.add_deprecated_argument(add_argument, argument_name, nargs)  
Adds a deprecated argument with the name argument_name.

Deprecated arguments are not shown in the help. If they are used on the command line, a warning is shown stating that the argument is deprecated and no other action is taken.

    Parameters:  
        • add_argument (callable) – Function that adds arguments to an argument parser/group.  
        • argument_name (str) – Name of deprecated argument.  
        • nargs – Value for nargs when adding the argument to argparse.

certbot.util.enforce_le_validity(domain)  
Checks that Let’s Encrypt will consider domain to be valid.

    Parameters:  
        domain (str or unicode) – FQDN to check

    Returns: The domain cast to str, with ASCII-only contents  
    Return type: str

    Raises: ConfigurationError – for invalid domains and cases where Let’s Encrypt currently will not issue certificates
certbot.util.enforce_domain_sanity(`domain`)  
Method which validates domain value and errors out if the requirements are not met.  

Parameters  
`domain`(str or unicode) – Domain to check  

Raises  
`ConfigurationError` – for invalid domains and cases where Let’s Encrypt currently will not issue certificates  

Returns  
The domain cast to str, with ASCII-only contents  

Return type  
str

certbot.util.is_wildcard_domain(`domain`)  
“Is domain a wildcard domain?  

Parameters  
`domain`(bytes or str or unicode) – domain to check  

Returns  
True if domain is a wildcard, otherwise, False  

Return type  
bool

certbot.util.get_strict_version(`normalized`)  
Converts a normalized version to a strict version.  

Parameters  
`normalized`(str) – normalized version string  

Returns  
An equivalent strict version  

Return type  
distutils.version.StrictVersion

certbot.util.is_staging(`srv`)  
Determine whether a given ACME server is a known test / staging server.  

Parameters  
`srv`(str) – the URI for the ACME server  

Returns  
True iff srv is a known test / staging server  

Rtype  
bool

certbot.util.atexit_register(`func`, *args, **kwargs)  
Sets `func` to be called before the program exits.  

Special care is taken to ensure `func` is only called when the process that first imports this module exits rather than any child processes.  

Parameters  
`func`(function) – function to be called in case of an error
